WITH so much writing and talking about making the most of vegetables, one may urge the need for more precise knowledge of cooking among working gardeners. Two defects are common—the ordinary methods of cooking vegetables are wasteful, and the most appetising and attractive qualities are either destroyed or they are not developed. During the war there has been some casual condemnation of boiling vegetables as against the simpler and better methods of steaming and baking. But it seems that gardeners do not know, and professed cooks do not know, and will not be told, which vegetables should be kept away from water or receive no more than may be converted into steam.

The Potato is not, or should not be, accepted for good and all as the only tuber or root to be grown and stored in bulk. For food, and family need for family need, the Parsnip is as sure, safe, nourishing, and can be served in as many forms as the Potato, and it would be more grown if the real value of this root, and how to cook it, were better understood. The Parsnip is spoiled by boiling; it is excellent if steamed; it is nourishing when baked dry or with fat or gravy, and sliced or clipped and fried it surpasses any Potato in downright flavour. Parsnips also make satisfying fritters, with or without bread crumbs or batter, and with the complement of Lemon juice cannot be distinguished from the best of Apple or Banana. In frying Parsnips they should be divided into two parts, as they are of two distinct qualities, the inner core, which is fit for soups and stews only, and the outer flesh, which should be cut lengthwise to form fillets or slices, for either baking, roasting, or frying.

Last year the present writer lifted about half a ton of Parsnips from less than four rods of ground. This crop was used in October till May, practically superseding the Potato, and formed the principal solid and mealy vegetable during the late winter and spring months.

Next to Parsnips gourds of various kinds should form substantial winter fare, as they do where their cooking is understood. Rippe Marrow and Pumpkin should never be boiled; it may be steamed till flowery, as a Potato, but it is far more attractive to the palate, and more nourishing, when cut into chunks or slices and baked or fried. Last season eighty large Marrows and fifty large Pumpkins. They will serve as a substantial winter and spring vegetable, keeping well into May. In these days the money value of this crop of gourds is at least a penny a pound, or say £6.5s., but, of course, the real gain is in the nutrient and the appetising value of this fruit as an extra winter vegetable, and it would be grown, dried, and used everywhere and by everyone if properly cooked and served.

Another valuable though neglected vegetable is the tuberosus Artichoke. Many people say they do not like it. They may bear telling that they have never tasted it at its best, but have been offended by the sloppy stuff which commonly appears on the table. Artichokes may be steamed, baked, roasted, clipped and fried, or grated to form a base for a purée, soup, or blended with bread crumbs, served en gratin, or fried dry after the manner of fish cakes. Allowing for the consistent cropping of the Artichoke, its soundness, keeping qualities, highly nutrient value, and the various ways in which it may be cooked, it is one of the best all-round vegetables for British gardens, small or large; but it will not have its full share in our economy till gardeners give proof that they understand the best methods of cooking it, and other crops they raise. A. C.

THE KITCHEN GARDEN

By J. DUNN, Foreman, Royal Gardens, Windsor.

TOMATOS.—Young Tomato plants intended to furnish ripe fruits early in spring are ready for shifting into 3-inch pots. The soil should consist of two thirds loam and one third leaf-mould, with sufficient sifted lime-rubble to keep the compost porous. After they are potted, grow the plants in a house having a temperature of 60°, and place them close to the root-glass. Keep the house closed until the plants begin to make fresh growth, but afterwards open the ventilators a little to cause the plants to grow stocky and short-jointed. Pot them again as soon as the roots have filled the small pots, and never allow the shoots to become drawn for want of ventilation. Plants in flower that will furnish ripe fruits in December and January should be grown in a house sufficiently ventilated to keep the atmosphere buoyant. Give the plants liberal supplies of liquid manure from the farmyard, and top-dress the roots with fine loam and a sprinkling of bone-meal, making the top-dressing firm by pressing with the hands as it is applied. Allow the plants plenty of room, and remove all decaying leaves and most of the side shoots, but retain sufficient growth to promote active growth at the roots. A temperature of 60° is suitable; open the ventilators a little in mild weather.

MUSHROOMS.—If fresh beds were spawned early in September there should now be a full supply of Mushrooms. Keep the temperature of the house as near 55° as possible, and maintain a moist atmosphere by damping the floor and walls daily with clear, soft water. Very little direct watering of the beds should be necessary, but if the surface should become too dry, rain-water may be applied through a can having a fine rose. Cold draughts must not be permitted, as these have a tendency to produce a dry atmosphere, which is detrimental to the crop. Continue to collect and prepare materials for the making of successional beds.

CELERY.—The final earthing up of this crop should be accomplished as soon as possible. Select dry days for the purpose, and make the soil as fine as possible previous to placing it round the plants with the hands, taking care to keep the centre of the plants quite free from soil and exposed to the air.

TURNSIPS.—All Turnips which are of sufficient size for use should be lifted and placed in a cool situation for use during the winter. Those which are intended for succession and are not far advanced may be allowed to remain in the ground until frost sets in, whilst those intended for consumption in the spring should be allowed to remain in the rows throughout the winter.

GROUND OPERATIONS.—Take the first opportunity when the soil is dry to wheel manure and other materials for enriching vacant land to sites where it will be used. Push on with the digging and trenching, so that as much of this work as possible may be completed in time for the soil to receive the benefits resulting from exposure to frosts. Heavy land which was manured for a previous crop should receive a heavy dressing of lime, soot, or burnt garden refuse, rather than another application of manure, especially if root crops are to follow. Ground intended for Parsnips, Carrots, and Onions will be benefited by a good dressing of soot applied now. The soil should be stirred deeply and the surface left as rough as possible.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to the Hon. ARTHUR J. DAVEY, Abbeots Wood, Godalming, Surrey.

FRUIT-GATHERING.—The majority of the Apples are ready for gathering and storing, but late Pears should be left until the stalk parts readily from the spur. Medlars are not, as a rule, ready for gathering before November, but one has to be guided to a great extent

† Dept. of Agric. Ireland.

† *Journal of Dept. of Agric.*, XVI, No. 2.

be the weather. These fruits should be harvested on a dry day, and laid thinly on stages. Place the "eye" downward, so that the stalks can be readily noticed, as decay always begins at the region of the stalk. Quinces are ready for storing, and the fruits should be handled carefully. They are used mostly for making jellies and marmalade. Late Plums should be gathered by this time. Cox's Golden Drop can be kept for some time to come; the fruits are delicious when kept till they shrivel. Place them in small, clean or new seed trays on a layer of tissue paper, and then stand the boxes one on the other. They will keep good in a dry room for several weeks.

INSECT PESTS. It may be that many Apples have fallen to the ground owing to injury caused by the grub of the codlin moth (*Carpocapsa pomonella*). Such fruits have a small hole near to the "eye," which leads to the pips or seeds. The marauder may have escaped by another hole near the stalk. After the damage is done, the grubs generally pass into the chrysalis form in the soil at the base of the tree till the next season, when the perfect moth emerges, to commence the cycle anew. The plan of placing grease bands around the trees is one of the best preventives of the winter moth, and banding is useful also in the case of the moth under notice if haybands or pieces of rough cloth are placed round the stems in July. Grease bands to catch the female winter moth should now be placed in position around the stems, if it was not done in October, and smeared well with a greasy substance that insects of the kind cannot cross. The soil under the trees should be dressed with gas lime, if procurable, or with quacklime. Sprays of alkali wash during winter do much to keep these pests under. The Apple sucker (*Psylla mali*) sucks the juices of the flower buds, causing the flowers to drop. The insects are very busy in October, when they may be seen pumping from leaf to leaf. They deposit their eggs in the crotches in the bark. Trees affected should have a thorough washing with petroleum emulsion as soon as the fruits have been collected. Plums, Currants, and Gooseberries will all be the better for a good wash with an insecticide applied on a fine, calm day. All kinds of ties which have done duty for the past year should be removed and dipped in a strong insecticide. When fixing new paper bands, they must be fitted quite tight to the stem, so that the pest cannot crawl under them.

FRUITS UNDER GLASS.

By I. S. HIRSH, Head Gardener at Ginnerybury House, Aston, W.

YOUNG VINES. Newly planted vines, of this, or the previous year or two, should be resting. There is often a tendency in these young and vigorous vines to make late growth; this is not desirable, and should be discouraged. Reduce the sappy wood in these instances, but proceed no further at present. Do not yet make any attempt at shortening the main rods on young vines; rather defer all this work until the leaves have fallen. Young vines in pots that are intended for earliest forcing and there is no better system should be well exposed for a few more weeks—say, until the end of November. During that time let them be pruned as the leaves fade and fall. Then, by early December, it will be safe enough to start them steadily in a moderate temperature with a view to obtaining ripe Grapes early in June.

THE COLD ORCHARD HOUSE.—Where the trees are of different kinds and planted in borders pruning may be commenced, with the exception of Peaches and Nectarines. Trees that have borne good crops of fruit will not need root-pruning, but this should be done in the case of those that have made gross growth and given little fruit, as soon as the top-pruning is finished. After root-pruning do not add rich soil, but a quantity of fine lime rubble, or crushed mortar, and use these materials only if a top-dressing is necessary. After the soil has been made firm water it copiously. Syringe the trees with a reliable winter insecticide. When the work is finished give the trees abundant ventilation.

VINES IN COLD HOUSES.—Even such late Grapes as Black Alicante should now be

cut, as presumably there will not be means of counteracting superfluous atmospheric moisture. Cut the bunches be cut and the stems placed in bottles filled with water. Keep them in a cool, dry room, and watch for deepening berries. Reduce the leaf-growth on the vines somewhat by removing all green, sappy shoots. Open the ventilators fully unless other plants are grown in the house. Let the remaining growth become well ripened and, as soon as the leaves drop, do the final pruning. After that apply a top-dressing, first giving a good soaking of water if the border is inside theinery, and then, if the vines have borne a good crop and need feeding, add a dressing of vine manure. Later on the rods should be cleared of loose bark and dressed with an insecticide.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

CLEANING THE HOUSES.—After the necessary repotting has been carried out advantage should be taken of any spare time to thoroughly cleanse the houses and plants, washing the glass both inside and outside. Before commencing the work, if it is convenient to do so, the plants should be moved to an adjacent compartment, to prevent the foliage from becoming soiled with the dirty water. Where this cannot be done, the house should be washed in sections and the plants protected with shading material suspended next to them. Soft soap should be mixed with tepid rain water, but not in sufficient quantity to damage the point. The soapy water should be syringed from the woodwork with clean water after the scrubbing is finished. The stage and walls should be scrubbed, also the pots. Before restating the plants should be cleaned of scale and other insect pests, and all diseased pseudo-bulbs and leaves removed. Any young growths that need support should be neatly tied to stakes; but not so tightly as to hinder the future development of the pseudo-bulbs or young growths.

EPIDENDRUM. Epidendrums of the radiosa type are suitable for cultivating in pots, and, when properly grown, their scendent growths will flower in a comparatively dwarf state, making the plants extremely useful for decorative purposes. Plants that have grown to an desirable length may have the top cut off the young growths about 2 feet in length, and eight or ten cuttings may be potted together in receptacles 7 or 8 inches in diameter. Place the stems about 6 inches deep in the pot, with as many of the aerial roots as possible. During the growing season train the new roots into the compost, which should consist of a mixture of peat or Osunda fibre and an equal proportion of Sphagnum moss. Grow the plants in the Cattleya or intermediate house near the roof glass. Give one copious watering after the plants are placed in the house; afterwards, direct waterings will not be necessary, as by frequently syringing the growths and aerial roots the compost will be kept sufficiently moist.

AERIDES.—Plants of Aerides that flowered early in the year may have the supply of water at the roots reduced gradually. Although these Orchids never entirely cease making leaf growth, it is important that they should have a short period of rest. If all through the summer the moss on the surface of the pots has kept fresh and green through frequent waterings, from now on through the winter the moss should be allowed to become a whitish green colour before water is again applied, giving only just sufficient to prevent loss of foliage. Aerides of the cooler-growing section, such as A. Schröderi, A. crassifolium, and A. Warneri, are still growing, and should be kept moderately moist at the roots for some time to come.

THE FLOWER GARDEN.

By W. J. GUISE, Gardener to Mrs. DEMESTRIE, Keele Hall, Staffordshire.

HOUSING TENDER PLANTS.—It may be advisable to retain most of the old specimen plants that were knocked out of their pots for bedding purposes. These should be lifted carefully, repotted, and placed in a close atmosphere for a

short time before removing them to cooler quarters. Tuberos-rooted Begonias should be lifted with plenty of soil, placed in boxes, and allowed to dry gradually. The soil must not be disturbed until they are required next spring. Winter the tubers under the plant stages in cool houses, in company with *Salvia patens*, Camass, and Fuchsias. See that drip from plants overhead does not reach them. *Lobelia cardinalis*, *Verbena venosa*, and *Echeveria* may be packed in boxes or shallow frames. The succulent *Echeveria* resents a close atmosphere, and air should be admitted during mild weather. The best of the Pelargonium plants lifted at once from the beds, short-rooted, packed in boxes in sandy soil, and placed in cool houses, will make fine plants for tubs, vases, or the centre of beds next summer.

SPRING BEDDING PLANTS.—The flower beds should be cleared of the summer bedding plants and prepared for the spring bedding plants. If the ground is dug thoroughly and a liberal amount of well-rotted manure and leaf-mould incorporated with the soil in equal proportions, it should not be necessary to manure the ground for the summer plants. Many effective schemes may be devised by the use of Wall-flowers, Polyanthuses, Arabis, Myosotis, Alys-sum, Aubrietias, Daisies and Pansies. Early Tulips, Snowdrops, Scillas, Juncquils, and late flowering Tulips may be associated with Myosotis, Polyanthus, Arabis, Aubrieta, and similar dwarf plants. Bulbs that show signs of rooting should be planted at once. Firm planting is necessary for all these plants, and the work should be done when the soil is in a friable condition.

GLADIOLUS AND OTHER BULBOSUS FLOWERS.—In cold, wet districts it is advisable to lift certain bulbous plants, or they may be injured by frost. Gladioli, Montbretias, Tigridias, and Galtonias should be lifted at once and placed in a cool frame to dry before storing them to the winter. Lifting may not be necessary near the sea coast or in light, warm soils, but some protection should be afforded the plants in cold weather by placing leaf-mould or stable litter over them.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to Lady NORTHCOLE, Eastwell Park, Kent.

THE PROPAGATING PIT.—As the season advances, many plants that have been grown in the conservatory during summer will have become rough and shabby. These old plants, if kept through the winter, require a considerable amount of room, and in view of this it is a good plan to propagate fresh stock from them, and discard the old plants. The finely coloured varieties of *Coleus* are still largely grown for summer decoration. Suitable shoots should now be inserted as cuttings in light, sandy soil, and placed in the warmest house. They will quickly form roots, and when sufficient have been struck the old plants may be thrown away. Pot the young plants into 60 size pots, using very light, open soil. Place them in a warm house, on a shelf in full exposure to sunshine. These small plants may be occasionally used for decoration. They will not stand cold, and must be returned to the warm house without undue delay. Other worn-out plants used for the edging of stages—such as *Isobea gracilis*, the variegated *Panicum*, *Pilea* in variety, *Tradescantias*, and *Selaginellas* may all be treated in the same manner, making sure that the young plants are well established before discarding the old ones.

STOVE CLIMBERS.—Give less water to *Allamandas*, *Gloriosas*, and *Clerodendron Balfouri*, reducing the amount gradually until, when the foliage has withered, it is withheld almost entirely. The soil in a border usually retains sufficient moisture during the winter to keep the wood from shrivelling, but plants growing in moderate-sized pots or tubs need an occasional light watering. Other warm-house climbers, such as *Stephanotis floribunda*, *Thunbergia*, *Clerodendron splendens*, *Heysa* and *Rondeletia speciosa* major, should also be watered very sparingly. As a general rule all climbers benefit by a rest during the winter.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.
 Editors and Publisher. — Our correspondents would oblige delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.
 Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, NOVEMBER 6—

Roy. Hort. Soc.'s Coms. meet. and National Clays Soc. combined show.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 45.7.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, November 1, 10 a.m.: Bar, 29.5; temp., 49.6°. Weather, Dull.

SALES FOR THE ENSUING WEEK.

MONDAY, WEDNESDAY, and FRIDAY—

Bills at 67 and 68, Cheap-side, at 1 o'clock, by Protheroe & Morris.

It is with the deepest regret that we record the death on the 27th ult. of Mr. Worthington G. Smith.

Worthington G. Smith, whose valued services to this journal are so well known to our older readers. Almost half a century has passed since this clever draughtsman first undertook the work of illustrating new and noteworthy plants for the *Gardeners' Chronicle*. The late Dr. Maxwell Masters had accidentally come across some of Smith's drawings of abnormal growths that had been prepared for illustrating Goethe's *Metamorphosis of Plants*. Dr. Masters' judgment in matters of this kind was uncommonly good, and he at once discerned the stroke of the master hand in Smith's early sketches. Smith's later work proved beyond doubt that he had no rival after the death of Walter Fitch, also a contributor to these columns. Beauty and firmness of outline, secured by long practice as an engraver, and accuracy of detail, rather than impressionist effect, characterised his work, and thus his drawings were far more valuable for practical purposes than those which aim at general and often fleeting effect. For many years Smith's drawings in the *Chronicle* constituted one of its most attractive features. If the reader will look at any of the numbers issued between 1875 and 1910 and examine carefully the illustrations of Orchids and other plants that the paper owed exclusively to Smith's skillful work, he will be struck by their wonderful accuracy. Being a careful and skilled botanist, he was able to sort out the essential organs, including pollen grains, and show them so magnified that the ordinary reader could form a perfectly correct idea of their

form and character. Many a time has the present writer sent the poorest possible specimens of a new plant of unusual value or novelty to Dunstable, with the request that Smith would prepare an illustration for these pages. No other material being available, it was that or nothing, and Smith, with his great knowledge of plants, was quick to appreciate the importance of making the best of them. He would place the specimens in water, fix together broken portions, and coax them by all means possible to again show some vitality. Seldom, indeed, did he say that he was unable to do what was asked of him. He could determine even from fragments what a plant had been like, and would

numberless researches into manners and customs, the weapons and tools of prehistoric man; indeed, his position as an archaeologist was a high one, and his published works on these subjects are permanent assets in the library of the student.

A marked and pleasant feature of Mr. Smith's character was his great sense of humour. It showed itself in almost everything he touched, and with his facile pencil he could convey it to paper. He was of too genial a disposition to use it often in any but a jocular vein, but in cases where it was employed to defeat an adversary its effect was extraordinary. We remember to have seen some political

FIG. 68.—THE LATE WORTHINGTON G. SMITH.

build it up as an anatomist would a damaged skeleton; but Smith excelled the anatomist, for he was able to make his plants "live" in their portraits. We do not remember a case where the effect was what artists term lifeless and dull.

His great pride in his work, and his consistent loyalty to the paper that he worked for and admired, will be always gratefully remembered by those who had the best opportunities of measuring his zeal.

Our late colleague was exceedingly versatile. He studied fungi with his usual thoroughness, and in the Natural History Museum are many of his drawings. He was a great antiquarian, and made

sketches prepared for election periods, sketches that well revealed his great ingenuity and fine humour. As an instance of the latter we reproduce in fig. 69 one of his drawings in which he represents himself as sketching for the *Chronicle* in conditions of some difficulty. It may be said that it is scarcely overdrawn, for he had sometimes to visit hot and moist houses and perform his work in temperatures as disagreeable as they were unfamiliar.

Worthington G. Smith was born on March 23, 1835. His first intention was to follow the profession of architecture, but in 1858 he abandoned architecture in favour of book illustration by wood engraving and lithography.

His published works include those following:—*Diseases of Field and Garden Crops* (1884), illustrated with 143 wood engravings; a supplementary volume to Berkeley's *Outlines of British Fungi* (1891); *Guide to Sowerby's Models of British Fungi*, 1891; *Man, the Primal Savage*, with 242 new illustrations; *Early Man in Bedfordshire*, contributed to the *Victorian History of the Counties of England; Dunstable and its Surroundings*, written for the Homeland Association, and *Synopsis of British Basidiomycetes*, containing 145 new illustrations. Deceased also prepared many water-coloured drawings of fungi and descriptive letterpress for various authorities, including the British Museum.

Naturally, Smith's great services to the public were acknowledged from time to time by the receipt of well-deserved honours. As early as 1865 he obtained from the Royal Horticultural Society a gold medal for coloured drawings of plants; in 1873 the Royal Horticultural Society of Ireland awarded him a silver medal; in 1874 he was presented with a box of silver plate by the Woolhope Club, Hereford, and in 1875 the Royal Horticultural Society's Knightian Medal in gold for his researches into the life-history of the Potato fungus, *Phytophthora infestans*. In connection with his studies of the Potato disease, it will be remembered that he claimed to have discovered the resting spores of *Phytophthora infestans* (see *Gard. Chron.*, July 10, 1875, pp. 35, 41), and the atheridium by whose contact it was fertilised, but the claim was contested by de Bary, a German botanist of the highest standing. In 1903 Mr. Smith was elected president of the British Mycological Society, and in the same year he became the first freeman of Dunstable; whilst in 1907 he was awarded the Voitch Memorial Medal in gold. He was awarded a Civil List pension in 1902 of £50 in consideration of his "services to archaeology and botanical illustration." Death took place at Dunstable, where he had lived since 1881, when he was compelled to leave London owing to heart trouble. He leaves two sons and one daughter; his sons are artists, and their business is the preparation of press photographs.

BELGIAN HORTICULTURE.—In an article by Professor LEPLEAE and Mr. VAN ONSOVEN the following methods of cropping are described as being practised in the market garden districts of Malines and Louvain, where the soil is light enough not to pack hard by treading: 1. Early Cabbage or Cauliflower inter-sown with Spinach or Cabbage Lettuce or with Radishes and Lettuces; 2. Carrots inter-planted with Cabbage Lettuce or Scorzoneria; 3. Early Potatoes inter-sown with Radishes, which are pulled before the Potatoes are earthed up; 4. Late Cabbage inter-planted with an early variety and marketed before the main crop is full grown. In general all vegetables which occupy the ground for some time are inter-cropped with Spinach, Early Carrots, Radishes, Chervil or Lettuce. Carrots are sown among

rows of Early Peas. Peas are often planted in every third or fourth row of a Potato crop. A single Pea seed is put in the centre of each Potato plant. The Pea and Potato grow up together, and the Peas are pulled out bodily on harvesting for using dry. The practice is not recommended where the Peas are to be used green, as picking would involve too much treading of the ground. Cabbage or Brussels Sprouts are often planted between the rows of all but very late varieties of Potatoes.

SUPPLIES OF SEED WHEAT.—The Food Production Department is offering farmers a

Seed Wheats will be ordered forward by the Food Production Department immediately on receipt of an order, and accompanied by a cheque for the requisite amount, provided that supplies are still available. Should the purchaser desire to have a sample of the Wheat the Department will send one, but this must necessarily involve some delay in the delivery of the seed.

THE DOUBLE-FLOWERED PEACHES.—It is worth while placing on record how abundantly the so-called double-flowered forms of *Prunus persica* have fruited this year. When the blossoms

FIG. 69.—THE LATE MR. WORTHINGTON. SMITH SKETCHING UNDER LIFTED PEAS.

special selection of Seed Wheat of the varieties known as Wilhelmina, Little Joss, Victor, and Brownk. The seed has been selected and cleaned with great care, and the percentage of purity is in no case less than 99. The selection was undertaken by a special committee under the direction of Professor BRYEN. Standing crops were inspected by these experts in all the English Wheat growing districts in order that only crops of outstanding quality might be chosen for the Department's Seed Wheat orders. The price of this selected seed is 9s. per quarter of 480 lbs. f.o.b., including new, non-returnable sacks. Supplies of these

soms escape the late frosts in spring. Fruits are occasionally seen, the most notable being the variety *foliis aureis*. This year, in common with most other fruits, the crop has been exceptionally good, the variety *flora-carnea* (syn. *rosea plena*) being the best. Quite tasty to eat raw, they are very nice stewed, and make an excellent jam, preserved at the rate of 1 lb. of fruit to 2 lb. of sugar.

MR. FRANK HARRIS, Superintendent of the Stockport Parks, has undergone an operation in the Manchester Royal Infirmary for an internal complaint. The latest report states that he is making satisfactory progress.

* *Journal of the Board of Agriculture*, XXIV, No. 6, sept. 1917.

ROSE AMERICAN PILLAR.—In respect to the remarks of Mr. EASTON on this Rose (see *Gard. Chron.*, September 3, 1917, p. 95), our old colleague, Mr. LEONARD BARROS, Editor of the *New York Garden Magazine*, sends us an interesting letter from Dr. W. VAN FLEET, the fortunate raiser of this popular Rose. Dr. FLEET states that "the variety was raised in 1893 from seed of a *Wichuraiana-Setigera* cross pollinated with a bright red Remontant Rose seedling, that had a touch of *Polyantha*, or, rather, *Rosa multiflora*, in its make-up. It thus contains the blood of four Rose species, but I regard it as essentially a *Wichuraiana-Setigera* hybrid. This variety appears to succeed under very diverse conditions."

ACTINIDIA AROUTA.—This vigorous growing climber is ripening fruits this autumn. They are green in colour, suggesting in size and shape a small Walnut. It is a fleshy, many-seeded fruit, juicy, and quite pleasing in flavour, emelling and tasting not unlike a second-rate Melon. Travelers tell us that the fruits are eaten in Japan and China, of which countries and the Amur region *A. arguta* is a native.

RETIREMENT OF MR. ALFRED GAUT.—We are informed that Mr. ALFRED GAUT, for many years lecturer on horticulture at the Leeds University, retires this week owing to failing health. Mr. GAUT, who has been an occasional contributor to these pages, is removing to Laburnum Cottage, Leigh Linton, Worcester, where he will be near to his son, who is Agricultural Organiser for Worcestershire.

THE HEAVIEST APPLE.—In regard to records of large Apple fruits and our instance quoted last week of a fruit, exceeding 2 lbs., Mr. G. M. TAYLOR reminds us that a fruit of Rev. W. WILKS variety, grown in the nurseries of Mr. GEORGE PYNE, Topsham, Devon, and picked on September 17, 1914, weighed 3½ ounces. But we have since been shown a still larger fruit by Mr. G. W. BYSON, The Brunds, Hild, Sussex. This was of Peasegood's Nonchuck; it weighed 2 lbs. 4 ozs., and measured 18 inches over eye and stalk and 17½ inches in circumference. We believe the fruit is to be shown on Tuesday next at the R.H.S. meeting.

BLACK LEG OF POTATOS.—The disease of Potatos known as Blackleg or Black Stem Rot is caused by bacteria. The symptoms appear in mid-June. The diseased plants are somewhat stunted and are rendered conspicuous by their pale green or yellow foliage. The upper leaves are apt to remain small, stiff and erect, and the margins of the leaflets are generally rolled inwards. The stems of affected plants are very easily pulled up, and are rotten and juicy black at the base. The bacteria (*Bacillus ptyophorum* or allied species) attacks the wood, and the disease may be recognised at an early stage by cutting across the stem and observing three brown spots—the woody spots of the vascular tissues—which show by their brownness that the disease is present in the plant. The leaves of affected plants turn brown, and the leaf-stalks die. If tubers form they will be found to be infected, and such tubers should on no account be used as seed. The diseased tubers are soft and discoloured, especially at the heel end; the flesh is brown and ultimately becomes wet and rotten. Tubers slightly infected at lift do not develop the disease in store, and may communicate it to sound neighbouring tubers. The disease is propagated by the use of infected seed, and the risk of this is heightened by the fact that slightly diseased tubers may appear on the surface to be quite sound. Experiments made in America show that diseased tubers may be disinfected by means of formalin. It is stated that the soil, once infected, may reinfect Potatos planted the following year.

* See *Journal of Board of Agriculture*, XXIV, No. 6, Sept., 1917.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

ROBINS IN MONMOUTHSHIRE AND AN ALBINO SPARROW.—The interesting note on the absence of small birds in a Surrey garden by A. N., on p. 145, reminds me of a somewhat similar case in Monmouthshire. A few weeks ago the local gardens were remarkably free of most birds. But there were large numbers of robins seen (and heard) everywhere. It has been said that robins suffered more than most birds from the severity of last winter. Then what can be the explanation? They would commence their warbling in the morning whilst we were still in bed, and would continue it all day; in the smallest cottage garden three or four could be heard at the same time. To find some of the other birds I turned to the fields where harvest operations were in progress, and there many could be seen in flocks, such as starlings, chaff finches, sparrows, and about any thistle ground where seed was ripening, numerous goldfinches would rise up as one approached them. So other birds had left the gardens almost entirely to the robins, and, according to custom, had become gleaners on the farms. The tiny village, situated about seven miles north of Abergavenny, under the shadows of the Skirrid, Sugarloaf, and Black Mountains, is extremely isolated, and the few houses are gathered round an exceedingly old church and yard, that at night serves as a playground for the numerous and particularly noisy owls. In the evening, almost before the robins had ceased their fussy, though low pitched warbling, the owls would fly around the church making the night audible with their weird cries. Since returning home I find that in our London garden two robins are daily visitors, also a light dove coloured cock sparrow. I suppose it may be regarded as an albino, but it is curious that the only really white feathers are about the head, where the normal male sparrow is coloured darker than elsewhere. *R. H. P.*

PLANTS FOR CARPETING BRICK RUBBLE.—Permit me to supplement the advice given to *Antonia* on p. 164. The best Sedums for the purpose and there are no better plants if a close carpet is required are *S. acre*, *S. anglicum* album, and *S. lydium*. For uniform distribution and the effective carpeting of the whole I know of no method to equal the following: Take a number of plants of either of the species named, carefully strip the fleshy leaves from their stems, and, after mixing them with soil, sow the mixture thinly broadcast over the area to be clothed. Should the interspaces between the rubble particles be large or rather deep a first sowing of soil alone should be given, which, while raising the level and preventing loss of water, will also provide ground for the young plants to root into. The Sedums named, like other members of the Crassulaceae, reproduce themselves from the bases of their leaves when these are detached intact from the stem; hence, the result of an hour or two of careful work may be expected to give rise to large numbers of plants. On occasion I have lightly rubbed the Sedums through a sieve, though I find stripping by hand a more satisfactory method. In the case of the *Aubrietia*, seeds mixed with soil would constitute the better way, and, indeed, the work had been anticipated, and quantities of cuttings had been rooted for the purpose. *E. H. Jenkins.*

MIRROW KALE (see p. 171). In reply to the inquiry by N. in your last issue, the outer covering of the fleshy part of the stems should be removed and the inner, narrower part cooked in the same way as Kohl Rabi or Turnips of any kind. This Kale and the new Superlative and Magnificent Swedes are valuable additions to the list of winter vegetables. *G. P. M.*

EARLY POTATOS In reply to T. (p. 172), I find the best early P.C.s for growing in pots, frames, and open borders, is Star of Reading. The stems are dwarf, and the variety gives a large crop on a small space. I consider it superior to Duke of York. *F. J. F., Bourne, Lincolnshire.*

APPLES AND PEARS GROWN IN 1779.—I am afraid that to quote, as I suggested in the *Gardener's Chronicle* of October 20, all the varieties of fruit mentioned in James Clarke's "Catalogue" of 1779, would take up more room than the Editors would care to allow. Perhaps, however, space can be found for the different varieties of Apples and Pears. I give the names *verb. et lit.*: Apples: Janting, Margaret, Red-streak, Codlin, Summer Scarlet Pearmain, Golden Pippin, Kentish Pippin, Nonchuck, 110-lan Pippin, Nonpareil, Royal Russet, Wheeler's Russet, Golden Russet, Ribston Pippin, Cat's Head, Golden Fennel, French Pippin, Winter Pearmain, Loam's Pearmain, Scarlet Pearmain, Lemon Pippin, Winter Greening, Aromatic Russet, Quince, Yorkshire Greening, Kitchen Renet, Prusse Worthy, "with many other sorts." Pears: Little Muscat, Green Chissel, Catherine, Jargonell, Chasse Madam, Windsor, Grosse Blonquette, Burree le Roy, Winter or Gray Burree, Autumn Muscat, Orange Bergamot, Harnden's Bergamot, Autumn Bergamot, Russett, Bonereton, Cresson, St. Germain, Swan's Egg, Chamoisville, Vergobuse, Black Worcester, Parkinson's Warden, Cadillac—the last three were baking Pears. I wonder how many of these varieties are still in cultivation? *J. Roberts, 18, King's Avenue, Clapham Park, London.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee

OCTOBER 25.—Present: Mr. E. A. Bowles, M.A. (in the chair), Dr. W. Bateson, Messrs. E. J. Allard, W. Hales, R. Hooper Pearson, J. Foster, E. M. Holmes, and F. J. Chittenden (hon. sec.).

Fruit of Trachycarpus ardens.—Mr. J. Fraser showed the immature fruits of this Palm from a tree in the open at Holland House, and remarked upon the distribution of male, female and hermaphrodite flowers, the fruits having developed from the last form of flower. Mr. Bowles said he usually found the last flowers to open were female, as they are in *Begonia* and *Aegle separaria*.

Vernon plants.—Mr. Bowles showed the fruit of *Lomera Hildebrandtii* from a cold green house at Earlham—a very large fruit for a member of this genus, measuring over an inch in diameter; *Rhodota his argentea*, with stalked heads of flowers; *Aklaria lobata* fruit, from Mr. Howard Baker's garden near Bristol; fruits of *Actinidia chinensis*, from Mr. P. W. Williams' garden at Lameth, Cornwall; fruits of the deep-flowered form of *Cyclonia Maulei*, to draw attention to their strong and pleasant perfume; fruits of *Arum italicum*, with the foliage, appearing this year unusually early; *Arum hydroclalum*, from the Holy Land; and that of a robust form of *Arum Dracontium*, all from Middleton House Gardens, where also came ripe fruits of the double red Peach, which has from 2 to 4 ovaries, and which bears twin fruits, of the purple leaved Peach, of the variegated form of *Cornus Mas*, and of the yellow fruited Yew.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

OCTOBER 4. *Committee present:* The Rev. J. Combeholme (in the chair), Messrs. R. Ashwood, D. A. Cowan, J. C. Cowan, J. Cypher, A. G. Ellwood, J. Evans, P. Foster, A. R. Handley, J. Howes, A. Keeling, D. McLeod, J. McNab, W. Shackleton, H. Thorpe, and H. Arthur (secretary).

AWARDS.

FIRST CLASS CERTIFICATES.

Loelia Cattleya Queen Marie ashlandensis (J. C. Walter, Gott's C. *avoca*), and *Cattleya Evansianae* (Coburns, both from R. ABEWORTH, Esq.

Cattleya Princess Royal var. Fair King (C. Fallon, C. Hardwood), from W. E. LEE, Esq.
C. Hindall var. Drapery Blue (*Gaskelliana albina* var. *Form Marlow* Bagnall), from Mrs. S. GREAVES.

AWARDS OF MERIT.

Loesia Cattleya Sappano (R. C. Mrs. Leaman C. *indusens*), and *Cypripedium Atherton*

Walker (*aurum Surprise* × *Gaston Balleché*), from Mrs. GRAVIER.

Cattleya talca sica (*Golden Oval*), *var. rosea*, and *C. Atrium albatensis* (*Harrietiana alba*), *var. David's* (*India*), from S. GRAVIER, Esq.

C. Fehaulti (*Fabia*), *var. Portia*, and *C. Fehaulti* *var. Champion*, from J. J. BOLTON, Esq.
C. Sghol nungwen, from R. ASHWORTH, Esq.

Laelio-Cattleya Adrienne (*L. C. Juno*), *L. C. St. Gothard*, from Dr. CRAVEN MOORE.

AWARDS OF ABERDEEN.

Odontoglossum cravenii (*alba*), 1st Class), and *O. amabile* (*ashlandensis*) (2nd Class), from R. ASHWORTH, Esq.

OCTOBER 13.—*Committee present*: The Rev. J. Crombieholme (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. C. Cowan, J. Callaghan, A. G. Ellwood, A. Hainger, F. Houghton, J. Howes, A. Keeling, D. McLeod, J. McNair, H. Thorp, and H. Arthur (secretary).

C. Hoeryana Bohiana, and *C. Naida* *var. superba*, from R. ASHWORTH, Esq.

Trichocattleya Lawsonia (*The Knobel*), *var. (L. trichocoma Walton Group)* *var. C. aurea*, and *L. C. Alce* *var. Golden Beauty* (*L. postiana*), *C. aurea*, from JOHN HARTLEY, Esq.

Cattleya Hoeryana Houghton's *var.*, from F. HOUGHTON, Esq.

Cypripedium Macul (*emithystrum*), from R. W. RICHARDS, Esq.

Bassia-Cattleya Lisette (*B. C. Merion*), *C. aurea*, from Messrs. J. & A. McBRIDE.

CULTURAL CERTIFICATES.

To Mr. S. FINDLOW, for a specimen of *Odontoglossum* (*var.*), having more than 70 flowers in Silver Medal also being awarded), and *Cypripedium* (*Charlesworthi* *Merle Dene* *var.*).

To Mr. C. BRANCH, for *Odontoglossum* (*Queen Maatke*).

GROUPS.

The following Medals were awarded to collectors: *Gold Medal* to W. R. LEE, Esq., Hey-

CROPS AND STOCK ON THE HOME FARM.

VARIETIES OF WHEAT.

THE selection of seed Wheat is an important factor. A change of seed from one class of soil to another will generally produce a larger yield than will seed from several grown on the same soil. Some types of Wheat which are successful in certain districts are failures in another. Therefore, the beginner would do well to ascertain the result of certain varieties in his locality, and act accordingly.

Clean seed Wheat is one of the most important of details. Some persons are content to sow any cheap Wheat as coming direct from the threshing machine rather than pay more for a clean sample. The cheaply purchased seed too often contains seeds of weeds and tacks in particular, which produce an after effect on the land not thought of at the time of sowing.

I do not propose in the present article to name nearly all the varieties of Wheat grown, but rather select a few suitable sorts for various purposes. Seedsmen publish in their catalogues en-

FIG. 10. BILBERIES, POLYANTHA, A NEW SPECIES FROM CHINA, WITH CRIMSON RED BERRIES (RHS. *Vegetable Month*, October 27, 1917, Sec. p. 103)

AWARDS

FIRST CLASS CERTIFICATES.

Cattleya Thora *var. Lavina* (*St. Mrs. Pitt*), *C. Empress Frederick*, *C. Fehaulti* *var. Prince of Wales*, and *Odontoglossum Queen Maatke*, from W. R. LEE, Esq.

Laelio-Cattleya Battoniana *var. Heliconia*, *Cypripis F. M. Bequest*, *L. C. Cambaniana*, *L. C. Mia* (*L. Fabia*), *L. C. Golden Oval*, *Cattleya Lavina*, *M. var. Wespary*, *var. tertia* (*alba*), from S. GRAVIER, Esq.

Cattleya pumila (*alba*), and *C. Veana* *var. Cyclops*, from R. ASHWORTH, Esq.

Cypripedium Charlesworthi (*Merle Dene* *var.*), and *Cattleya Marston* (*Abraham*), *C. Empress Frederick*, from A. J. OAKSHILL, Esq.

Cattleya Douglasii *var. superba* (*Fabia* × *gypsis*), and *Laelio-Cattleya Marston* *var. David* (*night*), from P. SMITH, Esq.

Odontoglossum Juno *var. Cromart*, from Dr. CRAVEN MOORE.

AWARDS OF MERIT.

Cattleya Sghol aurea, and *C. Boeringiana nungwen*, from J. J. BOLTON, Esq.

wood (to Mr. C. Branch), *Louise Silver Medal* to R. ASHWORTH, Esq., Newchurch (to Mr. Davenport), *Silver Medal* to J. J. BOLTON, Esq., Puddleton (to Mr. J. LAW), A. J. OAKSHILL, Esq., Bolton (to Mr. FINDLOW); Messrs. CYRIL AND SOSS, Cheltenham; and Messrs. SANDER AND SOSS, St. Albans.

ROYAL HORTICULTURAL OF ABERDEEN

The annual meeting of the members of this Society was held in the Music Hall Buildings, Aberdeen, on the 27th ult. Councillor Simpson presided. The balance sheet showed that the income for the year amounted to £17 7s., and the expenditures had been £15 3s. 5d. The surplus, when added to the balance of last year's accounts made a sum of £119 2s. 7d. to be carried forward. Great was expressed that no show had been held this year. Other bearers were elected as follows: Chairman, Colonel Gull of Dalchely; vice-chairman, Councillor Simpson; auditors, Messrs. W. Reid and W. Whyte; secretary and treasurer, Mr. J. B. Bennet. All the other nine bearers were re-elected.

gravings of certain varieties, which are a guide to the inexperienced as to which sorts to grow. One of the most complete lists that I know is that published by Messrs. Dunn, of Bournemouth, who show photographs of some eighteen varieties and give many interesting notes about each.

Food Standard meets the general requirements of a good miller's Wheat, with stiff, good straw, not so liable to be laid by wind and rain as some varieties. The colour of the grain is red, especially "strong" in well grown samples, and this is highly appreciated by millers. The variety was introduced by Messrs. E. Welsh and Sons, and will succeed on almost any soil. Square Head Masters is another popular Wheat for any soil, supposed to have been a cross of Scholey's Square Head and Golden Drop, selected by Mr. Teverson; thus it gets the name of "Teverson's Square Head." Broude, a white chaff red Wheat, of strong growth, originated and introduced by Messrs. Girden; this is an exceptionally good heavy yielding milling Wheat, which does well on most soils, but especially so on rich land. I shall never forget the sight of 12 acres of this Wheat in September last, on a farm which I inspected in the sea in this county.

Little Joss is a cross between Square Head Masters and Indian Ghurka, introduced by Professor Effen, who has done much to improve the breed of Wheats. This Wheat yields heavy crops of great strength of grain, and thus it is a most desirable variety to grow. Essex Conqueror, introduced by Messrs. J. K. King and Sons, is a popular red Wheat, yielding heavily from all soils. Universal is Messrs. E. Webb and Sons' latest introduction, which I grew this year, and from which I had 1½ sacks per acre, which, in an out-of-the-ordinary season like that of 1917, must be considered exceptionally good.

Yeoman is the latest of Professor Biffen's Wheats raised on the Mendelian system; it is said to be an exceptionally heavy yielder of red grain, and suitable for all soils.

Before the advent of roller mills white Wheats were popular in some districts, but owing to their not being generally so "strong" in the grain which roller milling requires more than other systems, they lost much of their value. A fault, too, in some varieties is that they have the habit of "sprouting" in the ear if there is much wet weather during the harvest, especially if the fields are "shut in" by woods, trees and high hedges.

Some of the newer varieties, I hear, are less liable to this defect, notably Benefactor (Messrs. Garton's), owing to the form formation of the grain covering. This is a strong-growing variety, yielding heavy crops, and is very popular. Victor is another of Messrs. Garton's introductions; gives heavy crops, while early cutting is said to be a deterrent against sprouting.

Andros Standup, introduced by Mr. Cole Ambrose, is a popular Wheat for sowing in January no less than in autumn. Carter's Standup yields heavily. I had 15 sacks per acre some few years ago. Burgess Fife produces especially "strong" grain, and can be sown quite late in the spring, perhaps with better results than when sown in the autumn. E. Malvern.

EDUCATIONAL FARMING.

The development that is now taking place in farming, and the changes in objects and methods that the present food situation is forcing upon the agriculturist, furnish good reasons for providing farm institutions and schools where young folks may obtain both practical and scientific education.

The ambitions of the Food Production Department in regard to the increase of acreage for grain and root crops will render necessary much more labour than was formerly employed. This labour will be paid higher wages than farm workers in these islands have enjoyed, and farmers will naturally expect in return better service than they have obtained heretofore. The sort of institution we have in our mind is that of a model farm, where mixed farming and dairying are carried out, and means provided for instructing students in the principles which govern the growth of plants, diseases, insects that affect their well-being, the value of deep cultivation, of irrigation, drainage, manuring, the comparative values of different manures and soils, also similar teaching in the management of cattle, sheep, pigs, and poultry, the making of butter and cheese, and last, but not of least importance, the buying and selling of live stock and crops.

A few weeks ago we inspected an institution farm at Usk, in Monmouthshire, that it is hoped will supply some at least of these requirements. The farm comprises 260 acres, of which 140 acres are pasture, 60 acres arable, and the remaining portion woods and copices. It was founded in 1915, under the provision of the Monmouthshire Intermediate and Technical Education Scheme, and is maintained from a legacy known as the William Jones' Foundation. The chairman of the Governors is Sir Henry Mather Jackson, Bart., one of the best known men in the county, and the principal manager is Mr. J. C. Newsham, who for some years successfully managed a similar institution in Hampshire.

Like most other institutions, this scheme of the Board of Education has suffered greatly from the war, as labour is scarce, and students of more than seventeen years cannot now be expected.

Accidentally, whilst the farm itself has been improved in many ways, and animal stocks have

been acquired that will be most suitable for the purpose the farm is to serve, other matters, including the building of a residential institution, have to be postponed indefinitely. For the present students occupy a roomy building with a fine lawn, which is bounded by the river Usk. Farm buildings have been erected which provide the best accommodation possible for stall-fed cattle, dairy cows, and pigs. The farm has a peculiar interest to gardeners because it is specially designed for the benefit of those who desire to unite with their farming more or less of gardening; hence its name, "Agricultural and Horticultural Institution." Ten acres have been laid out to furnish examples of vegetable cropping for the purpose of serving the market, also flower and fruit growing. In this garden manual experiments, rotation cropping, and other details of cultivation, together with comparative trials of the different varieties, are carried out. The soil is of the very best, and numerous young Apple trees prove by their wonderful crops of fruits, remarkable for their size, form, and colour. When times and things again become normal this farm should prove of very great value locally, and it may be hoped that similar ones may be established in other counties.

ANSWERS TO CORRESPONDENTS.

FUMIGATING A PLANT STOVE: *Correspondent.*

The best results are obtained when the houses are fumigated at dusk and opened on the following morning. The measurements of the house should be very carefully made and the exact amount of each ingredient should be used. The cyanide should be dropped into the acid direct by means of a suitable apparatus, and in no circumstances should it be enclosed in paper, which renders the process more than usually dangerous; nor, if sulphuric acid be employed, should it be enclosed in any metallic covering, which in the process of solution might assist reduction. In large houses several bowls should be used to ensure as even distribution as possible. The house should be tightly closed after the fumigation, and warning notices against entry should be placed on the doors. If sodium cyanide is used, the following proportions will be found satisfactory:—For green aphids: Sodium cyanide, ¼ oz.; phosphoric acid, ¼ oz.; water, ½ oz. for each 1,000 cubic feet. This will not search any plant. One application is sufficient. For black or white aphids, thrips and scale: Sodium cyanide, ½ oz.; phosphoric acid, ¼ oz.; water, 1 oz. for each 1,000 cubic feet. This will not search mature plants. One application is sufficient. For mealy bug and red spider in house of mixed plants: Sodium cyanide, 1 oz.; phosphoric acid, 1 oz.; water, 4 oz. for each 1,000 cubic feet. Some low young shoots may be affected at this strength, but to a very slight extent only. The following plants are the most susceptible to injury by the gas:—Adiantum cuneatum, Asparagus plumosus, Asparagus Sprengeri, Begonia Clavata, Begonia, Bromelia, Colchus thersifolius, Cyclamen in flower, Heliotrope, Mimosa pudica, Abachya bella, Marguerites, Salvia Bellifolia, Tacsonia, Cologynia cristata, and Odontoglossums.

GLASSES SURVEILLING: *H. G.* See reply to *G. Gray* in the last issue, p. 174, also Mr. Hudson's remarks on the subject in "Fruits Under Glass," p. 169.

NAMES OF FRUITS. In the naming of fruits, we desire to oblige our correspondents as far as we can, but the task would become too costly and too time-consuming were there no restrictions. Correspondents should observe the rule that NOT MORE THAN SIX VARIETIES be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. The fruits should be just approaching ripeness, and they should be properly numbered, and carefully packed in strong boxes; cardboard is often crushed in the post. Leaf or shoot of each variety is helpful, and in the case of Plants, Peaches and Nectarines, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. By neglecting these precautions, correspondents add greatly to our labour and run the risk of increased delay and incorrect determination. We do not undertake to send answers through the post, or to return

fruits. Fruits and flowering plants must not be sent in the same box. Delay in any case is unavoidable.

H. G. Winter Hawthornden.—*M. S. P.* 1, Madame Treve; 2 and 3, Marie Louise; 4, Beurre Diel; 5, not recognised; 6, Huyshe's Prince Consort; 7, Vicar of Winkfield.—*J. C.* 1, Beurré Capiaumont; 2, send fresh specimens later; 3, Beurré Clairgave.—*E. F.* 1, Mother; 2, D'Arcy Spice; 3, Cornish Aromatic; 4, Braddick's Nonpareil; 5, Cox's Orange Pippin; 6, White Nonpareil; 7, Green Blenheim.—*G. B.* Pear, Marie Louise; Apple, Winter Quarrenden.—*Dr. P. P.* 1, Calville St. Sauveur; 2, Early Nonpareil.—*F. J. H.* 1, Mere de Menage; 2, Stirling Castle; 3, Bramley's Seedling; 4, Lady Heniker; 5, Lady Lennox; 6, Ben's Red.—*P. B.* 1, Cellini; 2, Beauty of Kent, Wyken Pippin.—*J. H. B.* 1, Lady Lennox; 2, Beurré Superfin; 3, Beauty of Kent; 4, 5, 6, Dumelow's Seedling (syn. Wellington).—*H. C.* 1, Decayed; 2, Marie Benoist; 3, Marie Louise; 4, Glou Morecan; 5, decayed; 6, Madame Treve.—*J. G. D.* 1, Emperor Alexander; 2, Maik's Collin; 3, Northern Greening; 4, Beurré Rance.—*H. S. K.* 1, Worcester Pearmain; 2, Summer Strawberry; 3, Nonesuch; 4, Golden Knob; 5, Hambleton Deax Amis; 6, Fearn's Pippin.—*T. C.* 1, Sandringham; 2, Melon Apple; 3, Hanwell Searing; 4, Stirling Castle; 5, Jolly Beggar; 6, Anne Elizabeth.—*J. R. B.* Pear, Pitmanston Duchess.

NAMES OF PLANTS.—*Correspondents not answered in this issue are requested to be so good as to consult the following number.*
E. S., Beigate. Ginkgo biloba, a member of the Coniferae, and not a Tree Fern.

PEAR WITH SPOTS: *J. H. B.* The fruits are attacked by scab disease, caused by the fungus *Venturia pirina*. Spray the trees with Bordeaux mixture at half the usual strength, when the buds are beginning to open, repeating the operation when the petals are falling from the flowers, and again when the young fruits have attained the size of Peas.

POTATO: *J. H. E.* Potatoes cannot often be named from single tubers. It is necessary to know the habit of growth, colour of flower, season of ripening, and other details which only the grower can determine.

REMOVAL EXPENSES: *H. H.* In accepting the sum of £10 towards the expenses of removal you agreed to stay with your employer if things were satisfactory. Now, at the end of two months, you wish to leave him, and the employer expects you to forfeit the ten pounds be advanced to you. So far as the legal point of view is concerned, we imagine you would have to be in a position to prove that things were not reasonably satisfactory and that in consequence your promise to stay in the service is no longer binding. Whether you are in such a position we are not able to judge. It may be assumed, however, that in private service the employer would be given the last judgment on whether certain operations in the garden were necessary or not, although his decisions were not what most people would consider appropriate to present circumstances.

TALLY OF CABBAGES: *Smith.* A tally of Cabbages is sixty heads.

WEED ON A LAWN: *A. T. H.* The Creeping Buttercup, *Ranunculus repens*, is one of the most difficult weeds to eradicate. It increases by runners, forming offsets, and has a very vigorous root-system, making it a difficult matter to destroy the plant by hand-weeding. The application of a nitrogenous manure in the spring, such as sulphate of ammonia, would cause the grass to grow luxuriantly at the expense of the weed. Afterwards rigorous hand-weeding, marking out the lawn in squares, and weeding each square separately, should effect a clearance of the pest.

THE GARDENERS' CHRONICLE occupies a position in the world of horticulture which is absolutely unique. Founded in 1841, in the very dawn of the horticultural era, it has advanced step by step with the gradual development of horticulture in the country. Its pages were men of high distinction. Sir Joseph Paxton, the greatest gardener of his day, Dr. Lindley, the brilliant botanist, the late Sir Charles Barry, with his superb English house of gardens, these are among the little group of men who launched the "Gardeners' Chronicle" on a long and prosperous voyage. The paper has a fine and inspiring tradition to maintain, and has progressed from the first progress reported by the first issue of the "Gardeners' Chronicle" to the confidence of its readers, and the confidence it still enjoys.

SANDERS, Orchid Growers,

St. Albans.

THE HORTICULTURAL DIRECTORY AND YEAR BOOK is now being prepared, enlarged and brought up to date. This work, the copyright of which was purchased last year by the Gardeners' Chronicle, Ltd., was then thoroughly purged of all out-of-date and useless names, but during the past year there has been so many changes among Gardeners, many of whom have joined the Army, it is therefore again being subjected to a thorough revision, besides which large numbers of fresh names are being added. All who desire a full up-to-date guide to the horticultural world will do well to write to 41, Wellington Street, W.C. 2, at a once. The new edition will be ready in December, price 15s. 4d. post free.

SITUATIONS VACANT.

Four Lines 3s. (Head-line counted as Two), 6d. for each succeeding line.

Gardeners desiring their Advertisements repeated must give full particulars, otherwise no notice will be taken of their communications. Name and address alone are insufficient.

GARDENER (HEAD) seeks engagement in a good establishment, where several scholas are kept, life experience in all branches, highly recommended by present employer, A. W. Gilmour, Esq., after 11 years service, leaving through peace being sold, married, age 44, near London preferred. Apply, F. BARKER, The Gardens, Avery Alberts House, Brickford.

HEAD GARDENER, where several are kept, 27 years' experience in good establishments, excellent references, 11 years' Head, no children, discharged, C. REED, 170, Stanley Road, Tootingdon, Middlesex.

GARDENER (HEAD) desires re-engagement in good establishment, age 33, thoroughly experienced in all branches of the profession; good references, 6 years' Head, no children—State wages and full particulars to W. EAST, Upper Hill Gardens, Tottenham, Herts, N. 20.

SIR HARRY NORTH, Lemon Well, Fitcham, Kent, highly recommends a first-class HEAD GARDENER, practical expert in every branch of Horticulture and capable to any extent, at liberty.

GARDENER (HEAD), in good establishment, large and varied experience in all branches, 10 years in present situation, age 43; married, G. B., Box 4, 41, Wellington Street, Covent Garden, W.C. 2.

SITUATION required as GARDENER, Head or Single-hand, experienced, good testimonials—GARDENER, Stoke Cottage, Green, Tonbury Walk, Singapore.

GARDENER (HEAD WORKING, where one or more are kept), thoroughly experienced all round, Inside and Out, married (no family), age 33, good references—State wages, T. W. SUTTON, Hill Lodge, Pitt grates Way, Westcliff, Kent.

GARDENER (HEAD WORKING); life experience in all branches, good references, 21 years present place, age 50, GEORGE BEALE, The Knowle, Virginia Water, Surrey.

ORCHID GROWER and WORKING HEAD GARDENER desires re-engagement, 32 years present situation, good all-round experience, over military age—State wages, &c., to CONINGSBY, Adocks Leigh, Bristol.

GARDENER (HEAD WORKING or good SINGLE-HANDED), life experience in all branches, age 51, married (no family), BICKER, The Cottage, Church Mead, Fribright, Surrey.

GENTLEMAN (50) desires WORKING MANAGEMENT, Farmery, Gardens, Small Estate, Food Production, Fruit, Vegetables, Tomatoes, Forge Crops, Cattle, Sheep, Higs, Boring, Sewing, Accounts, excellent references, B. Box 36, 41, Wellington Street, Covent Garden, W.C. 2.

SITUATION required in Pleasure Grounds and Kitchen Garden, where one or two are kept, age 48; single—A. HOLLAMBY, 42, Wellfield Road, Stratford, S.W.

DISCHARGED Soldier seeks situation; experienced Inside and Out, married (no family); Single-handed or otherwise.—Apply, F. CORDERY, 1, Rothern Road, Catford, S.E.

JOURNEYMAN (INSIDE) seeks Situation in good place, age 22, discharged from Army; experienced in Fruit and Plants, excellent references.—Apply, F. WILLIAMS, Eaton Bishop, Herefordshire.

HEAD GARDENER (Lady) requires re-engagement; highly trained, England and France, 10 years' experience, thorough knowledge all branches; accustomed to management of large establishments.—C. M., Box 11, 41, Wellington Street, Covent Garden, W.C. 2.

LADY GARDENER seeks Post; college trained and experienced, Vegetables, Fruit, Glass, non-resident, alone or with others, A., Box 14, 41, Wellington Street, Covent Garden, W.C. 2.

TWO LADY GARDENERS desire post together, one as Head, with 11 years' experience, Stanley Diploma, first-class, R.H.S., Dairy, Poultry, Bees, the other as Under, with 8 months' training on Market Garden, some Glass, F. F., Box 12, 41, Wellington Street, Covent Garden, W.C. 2.

UNDER GARDENER—Lady, taking short course, horticultural training, seeks Post under experienced Head, Vegetables for market or in station preferred.—Address V., Horticultural College, Chester.

TRADE.

MANAGER for large Market Garden or Nursery; Outside, chiefly Vegetables and Hardy Fruits, Inside, Grapes, Cucumbers, Tomatoes, &c., highly efficient and capable; Midlands preferred.—"PRODUCE," Box 13, 41, Wellington Street, Covent Garden, W.C. 2.

SEED and FLORAL TRADE.—Advertiser seeks situation as MANAGER, HEAD SHOWMAN or MARKET SHOWMAN, 22 years' thorough practical experience in all branches; 13 years' last situation; age 39, married, discharged from H.M. Forces; London preferred, J. N. PEARCE, 36, Kellerton Road, Lee, S.E.

TOMATO and CUCUMBER GROWER seeks situation as FOCUMAN; 15 years' experience with leading growers in London district, ineligible for Army, age 39.—C. ANDERSON, 62, Newmarket Road, Cambridge.

LADY GARDENER, aged 23, with practical experience seeks appointment, Market Nursery in Home Counties preferred, or under good Head in private place for Vegetables and Fruits under Glass. Apply, E. L., Box 21, 41, Wellington Street, Covent Garden, W.C. 2.

FLORIST, having for a considerable time been employed of first-class West-End business, used to buying, seeks situation at a shop or hotel, or as sub-station.—W. S., Box 6, 41, Wellington Street, Covent Garden, W.C. 2.

FLORIST—LADY seeks re-engagement as MANAGER or FIRST HAND, first-class references, H. M., 34, Albert Road, Hylle, Kent.

BULL'S FOOD FOR PLANTS, FRUIT & VEGETABLES.

CANNON HALL MUSCAT

Grown with Bull's Food for Plants
at Menpes Fruit Farm.

MENPES FRUIT FARM, LTD.

Dear Sirs,
For many years we have exclusively
used your Food for Plants for our
Vines, and the results have invariably
been all that could be desired.
Please repeat our last season's order
and oblige,

Yours faithfully,
For Menpes Fruit Farm, Limited,

J. E. Peters
Manager.

NOTES FROM A GALLOWAY GARDEN.—XIII.*

I HAVE read with pleasure Mr. Edwin Beckett's praise of *Hibiscus syriacus* (p. 157). There is, indeed, no more beautiful late-flowering shrub than some of its varieties; but Mr. Beckett's statement that it will succeed "in almost any soil or locality" must be accepted with reserve, for, alas! it delays its display too late for the generality of Scottish gardens. It may be coaxed forward by training it against a sunny brick wall; but that is almost an indignity for a plant that is as hardy as a Box bush. It is one of the peculiarities of our north-western coast climate that, although growth is often more forward in February and March than it is in the southern and midland counties, it invariably lags behind them after midsummer, as much as three weeks or a month. This is not owing to want of sunshine; during the summer of 1917 we enjoyed far more bright sunshine in Galloway than was vouchsafed to Kent and Surrey; but our sunshine differs in quality, owing, I suppose, to the greater humidity of the atmosphere of the Scottish west coast. In bygone years, when the House of Commons prolonged its dreary sitting through and beyond the dog days, many a time I used to repair to Chyne Walk, Chelsea, to refresh my eyes with the sight of a great bush of the Syrian *Hibiscus* the variety with white flowers and a maroon purple blotch—growing and blooming profusely in the forecourt of one of the houses near the east end of that delightful row. And when, at length, I got back to Scotland, the flower buds on our bushes were hardly showing colour, except on the wall of Mr. Wallace's house of Lochruan, trained against which was a fine *Hibiscus* with violet flowers, worth going all the way to see in September. In some gardens, our own, to wit, wall space is hard to come by, all avail-

able exposure being already occupied by things which one cannot make up one's mind to displace. So we have to forgo several shrubs and herbs which brighten more southerly borders—*Hibiscus* in all its charming varieties, *Caryopteris Mastacanthus*, *Tourneria frutescens*, *Perovskia atriplicifolia*, and, among humbler growths, the goblin gold of *Sternbergia* and the flames of *Lobelia Cavanillesii*. To the other side of the account may be set the preference shown for our climate by Himalayan and Chinese *Rhododendrons* and many beautiful Chilian plants, besides the longer duration of blossom, owing to the sunshine being less scorching than in a drier atmosphere.

If Mr. Reginald Farrer had sent home no spoils from his Chinese expedition other than the *Gentian* which bears his name, he would have earned the enduring gratitude of stay-at-home amateurs, for it is the lordliest of all the autumn-flowering species of that genus. It is a glorified *G. ornata*, excelling that species in vigour and the size of its flowers, which are sky-blue, of the same celestial quality as that distinguishing the best forms of *Meconopsis latifolia*. The interior of the throat is shell white, the outside palest buff, vividly striped with dark blue, almost black, lines, like the waistcoats worn by footmen in undress livery, before they all went off to join the Colours. Its requirements seem to be simple. We placed a small plant which came here last spring at the edge of a bed occupied by Lilies and Asiatic *Rhododendrons*, giving it a berth of sharp loam with a little peat, surfaced rather thickly with small gravel. It has made excellent growth, and bore two flowers in October.

Mr. Arnott's timely note on Autumn Crocuses (p. 167) comes to remind one how little use is made of these pretty flowers. One may perambulate fifty gardens with out being cheered by the sight of any of them; *Colchicums* in plenty, with their six stamens, but no Crocuses, distinguished by having only three. I fancy the reason for this unmerited neglect is that most people order their bulbs in autumn, after these Crocuses have started growth, which continues throughout the winter months. The only season when the corms will suffer transport without injury is in summer, after the foliage has died down. But that is just the time when nobody has a thought for Crocuses.

At this season, late October, the glistening flower-buds and growth buds of *Rhododendron barbatum* are thickly covered with the corpses of flies of various kinds. I wish someone skilled in the use of the microscope (which I am not) would hold an inquest upon the dead, in order, if possible, to ascertain whether the slaughter is purposeless or to the advantage of the plant. Some years ago I propounded the question to a high authority on vegetable physiology, and received in reply an assurance that the analogy between the capture of flies by this *Rhododendron* and by such plants as *Drosera*, *Pinguicula*, and others, was merely superficial; that the strong bristles on the petioles (which certainly hinder the insect's

efforts to get free) were not glandular, and therefore incapable of conveying nutrition to the plant. He referred me to the shining, glutinous buds of the Horse Chestnut as truly analogous to those of the bearded *Rhododendron*, and unfruitively functionless. Against this it might be argued that Horse Chestnut buds do not get sticky nor shine in a manner to attract insects until the leaves have fallen and few flies are about, whereas those of the Bearded *Rhododendron* are sticky and shine from the moment they appear. Moreover, I have never seen insects caught on the buds of the Horse Chestnut. Wherefore this morning, when I stood before a thirty-year old bush of *R. barbatum*, 9 feet high and 10 feet through, with every one of its flower and growth buds thickly plastered with dead flies and here and there a dead spider, the ejaculation of the disciples about the alabaster pot of ointment rose to my lips—"To what purpose is this waste?" It is difficult to believe that the plant derives no benefit from such a holocaust. Some other species of *Rhododendron* catch flies, but not so systematically as *R. barbatum*. I have seen a considerable number of insects adhering to the young shoots of *R. Griffithianum* (Aucklandii) in early summer. A kind friend whose attention I invited to this problem sent me a plant of the Chinese *R. habrotrichum*, whereof the young growth and leaf-stalks are densely covered with hairs; but it is not so sticky as *R. barbatum*, its hairs are softer, so it has succeeded in capturing only a few insects.

We were afflicted on October 21 with a very heavy gale, which, being accompanied by a pretty severe frost, has wrought a lamentable change on the landscape. In the woodland, Oaks have suffered most, for they were still carrying full sail. Many have been uprooted, and more have lost limbs. When I left home on October 15 there was a finer promise than usual of autumnal colour; when I returned on the 26th, much of the foliage had been stripped off, and much of what was left had been scoured into ashen brown by the combinations of violent wind, sea spray and frost. In the garden, which I left gay with *H. T. Roses*, *Cherodendron triebotomum*, *Hypericum patulum* and *Hookeri anum*, scarlet and carmine *Lobelias*, white *Cimicifuga simplex*, *Salvia patens*, *Aconitum Fischeri*, and a rigidly select sprinkling of Asters, almost the only things that remained bright and cheerful were *Berberidopsis corallina*, *Abutilon megapotanicum*, and a few *Hydrangeas* in sheltered nooks.

Chief source of disappointment was missing the annual display of *Cercoidiphyl-lum japonicum*, which the frost had stripped of leaves just as they were beginning to turn. The plant on a wall at Kew gives no idea of what the species is capable. Ten or twelve years ago I received a packet of seed from a friend, which produced some thousands of plants. In the second autumn the seed-bed resembled a luminous carmine carpet. We know nothing about the status of the thing, nor of its requirements; wherefore, in virtue of

* Previous articles appeared in the issues for Jan. 13, Feb. 7, Mar. 10, April 14, April 28, June 2, June 30, July 21, Aug. 18, Sept. 8, Sept. 29, and Oct. 20, 1917.

its wonderful autumnal colour, we treated it as a shrub, disposing it at the back of flower borders and along woodland paths. Nor was my ignorance of its true nature dispelled till I happened to read in *Traveler's Notes*, by the late Mr. James H. Veitch, that he found a tree of *Cercidiphyllum* near Sapporo, in the north of Japan, measuring 21 feet in circumference of stem! Meanwhile, the plants remaining in the nursery had become drawn and ill-rooted. We endeavoured to establish them under forest conditions, but at least fifty per cent.

PHELLODENDRON SACHALINENSE.

Four species of *Phellodendron* are in cultivation: *P. amurense*, a native of Amurland and Manchuria; *P. chinense*, introduced from W. China by Mr. E. H. Wilson, both fruiting freely this year; *P. japonicum*, a species from China and Japan; and *P. sachalinense*, a native of Japan, Corea, and Saghalien. The behaviour of *P. sachalinense* suggests that it is the most

and smooth beneath, while those of *P. japonica* are very downy on the underside.

P. sachalinense appears to have been first introduced to Britain from the Arnold Arboretum in 1899. Seeds provide the best method of propagation. The trees thrive best in a good holding, loamy soil. A. O.

THE MARKET FRUIT GARDEN.

In October only eight days of twenty-four hours were entirely free from rain, though on one the quantity was under one-hundredth of an inch, and therefore classed as unmeasurable. There were 22 rain days at my place, the total fall being 4.29 inches. The total was not as great as that of October, 1916, when 21 rain days gave 5.47 inches. The frequency of the rainfall was more unfortunate than the quantity, as the land was kept constantly wet, and unfit for cultivating or hoeing, and the rampant weeds continued to flourish. Moreover, the gathering of the later portion of the Apple crop was delayed to great disadvantage, so that when we came to pick a great crop of Lane's Prince Albert in the last orchard to be cleared, fully two-thirds of the Apples were on the ground.

SLUGS EATING APPLES.

A great number of Apples which were blown or fell off the trees had small holes eaten in them by slugs. This damage, never before noticed to any considerable extent, was due to the wet and weedy condition of the orchards.

A SEASON OF WASTE.

My memory does not recall any previous season in which the waste of fruit grown has been nearly as great as it has been this year. First the tremendous gales of August 24 and 27 blew down tons of Plums, Apples, and Pears, mostly immature, and therefore saleable only, if at all, at very low prices. Afterwards, occasional strong winds did further damage, and later still the delay in the gathering of Apples due to the almost constantly wet weather of October, already alluded to, added to the great proportion of "drops." Even when Apples fall upon soft ground or grass, many of them are bruised by hitting branches when falling, and others are injured by various pests, or gnawed by rabbits. My pickers are instructed to keep "drops" separate from gathered fruit, as far as possible, and the former are marketed first. If not soon disposed of, the waste in rotting is very serious, and this year the proportion of "drops" was so tremendous that many weeks elapsed before all could be packed, so that the proportion of unmarketable fruit was very large. Adding to this misfortune the unprecedented attack of caterpillars in the blossoming season, which prevented the formation of fruit to an enormous extent, it must be concluded that the season has brought forth an uncommon series of misfortunes. There is no doubt that, but for the caterpillar attack, the crop of Apples would have been one of the greatest ever known. As it was, and in spite of all mishaps, the yield turned out surprisingly large. There were some tremendous crops in some varieties, notably in Royal Jubilee and Lane's Prince Albert, and the extra size of the fruit in varieties that did not bear thickly, partly compensated for the reduction in number. Nearly all the gatherings gave results above expectations, and when prices rose after the glut of "drops" had been sold, the returns of the Apple crop became satisfactory.

SOME RESULTS OF A WET SEASON.

While the extra size of Apples may be attributed partly to the wetness of the season, though the thinning of the crop by the misfortunes alluded to above must also be taken into account, there were also disadvantages due to the former condition. One of these was the coarsening of the quality of such choice varieties

(Photograph by E. J. Wallis.)

FIG. 71.—FRUITING BRANCH OF PHELLODENDRON SACHALINENSE.

succumbed. Of the rest, I shall be older than it is pleasant to contemplate before being able to report one, not 21 feet, but 21 inches in circumference! Besides the gorgeous display *Cercidiphyllum* makes in ordinary autumns, it is very attractive in spring, the young foliage being of a bright, rosy-fawn colour.

Among the things uprooted by the gale is a common Spindle tree (*Euonymus europaeus*), of the unusual height of 27 feet. Seldom has *E. latifolius* borne such a profusion of its bright fruit as this year. *Herbert Maxwell, Monzieith, Scotland.*

amenable of the four species to cultivation in this country. It is a deciduous tree, presumably of moderate height; the specimen from which the spray illustrated in fig. 71 was taken is about 20 feet. As a pleasure-ground tree it has attractive foliage, the leaves, consisting of 7 to 12 or more leaflets, up to about 1 foot in length. The panicles of greenish-yellow flowers are not showy, but in autumn, quantities of black fruits, $\frac{3}{4}$ inch in diameter, give the tree an attractive and interesting character. From its nearest ally, *P. japonicum*, it is readily distinguished by its leaflets, which are narrower

as Cox's Orange Pippin and a few other sorts. Another was the development of scab, particularly in Cox's Orange Pippin.

The most characteristic result of the wet season, however, is the extraordinary prevalence of sooty blotch on Apples, and particularly on Cox's Orange Pippin, a large proportion of which is disfigured by the black fungus. The sooty blotch can be rubbed off with a rough duster.

RECORD WEIGHT OF AN APPLE.

The greatest weight of an Apple of which I have read is 2 lb. 5½ oz., reported of a Gloria Mundi sold in Covent Garden by Messrs. Garcia, Jacobs and Co., on October 27, 1915, at the probably record price of sixteen guineas. There were six specimens, but only one was put up to auction, the five others being presented to the purchasers, Messrs. Adams and Co., Bond Street, London. The Apple was grown at Ten-Terden, Kent. The grower's name is not mentioned in the paragraph from which I quote, cut from the *Fruit Trades' Journal* of November 1, 1915.

THE TOXIC THEORY.

Judging from the account of the experiments carried out by Mr. Spencer Pickering, given on p. 170 last week, one very important test of the supposed toxic effect of one plant upon the same or another plant was lacking. The drainage from a tray containing Mustard, for example, into a pot in which a Mustard plant was growing, injured the latter; but, as there was no trial of the effect of drainage from a tray containing soil only, the evidence of the toxic effect of drainage from the Mustard tray is not conclusive, as there is nothing to show that the same injurious effect upon the plant in the pot would not have been caused by drainage from bare soil. As to the idea that grass under trees suffers from the toxic effect of the roots of the trees upon it, a much more simple and probable explanation is available, namely, that of the shading effect of the branches and foliage, together with the competition of the roots of the trees with the grass for the nutritive constituents of the soil. Conversely, the corresponding competition of the grass with the roots of the trees for the elements of nutrition may account in great measure for the failure of trees in grass to grow as vigorously as trees in arable land. The toxic theory seems to me to be equally forced by concluding that it accounts for the inferior growth of three Mustard seedlings planted in a pot containing three established Mustard plants. The latter had spread their rootlets over a good part of the soil, and so were able to take the lion's share of the nutritive ingredients. Similarly, when trees are planted in an established orchard to fill up gaps where older trees had died, they seldom flourish, although care has been taken not to plant the new trees in the precise sites of the old ones. The new ones have a very poor chance of proper nutriment when the roots of the old ones are all over the ground, or nearly so. The result is the same when fruit bushes are planted in an established orchard, even when the trees are only a few years old. I have an orchard in which Gooseberries were planted at the same time as Cobnuts and Plums. They grew and fruited well for a few years, and then were attacked by collar rot, and had to be grubbed up. They were replaced with Black Currants, which never grew even tolerably, as the roots of the trees had almost complete possession of the soil. Lastly, as to the supposed toxic effect of a plant being greater upon a plant of the same kind than upon one of a different species. Here the more simple and reasonable explanation is that plants of the same kind are competing against each other for precisely the same proportion of the several elements of soil fertility, whereas plants of different kinds do not compete with each other to the same exhaustive extent. The late Mr. Mechi, of Tiptree fame, when advocating the thin sowing of Wheat, used to point out that one Wheat plant was a keener competitor of another than any other plant would be. *Southern Grower.*

PERGOLAS.

(Continued from page 176.)

I SHOULD feel inclined to disregard the well-discussed question of planting if it would not savour too much of "Hamlet" without the Prince.

In addition to the great number of climbing plants available, many shrubs of pliant habit are quite suitable for use on a pergola. The field of choice is therefore so large as to be confusing unless some clear principle of arrangement is followed. Most climbing plants when really happy make up in luxuriance what they lack in backbone. Over-crowding leads to a muddled effect, and it is better to exercise restraint in planting.

limit its reign of glory to a comparatively short burst of Rose bloom. If other plants are also introduced in which the tints and texture of the foliage are considered, the sum of the season's enjoyment is considerably increased. Density of foliage at calculated points is important in producing effects of perspective, and the flecks of sunlight and bars of shade on the pergola floor give character to the interior. A heavy evergreen at the entrance will make an inviting contrast with the outside glare, or a good result follows the planting of a rampant climber, such as a vine, which will sprawl over the first arch and clutch also at some architectural feature to which the pergola is keyed. Planting which helps to unify a pergola with its surroundings serves a good purpose.

FIG. 72. PERGOLA FURNISHED WITH CORDON PEAR TREES

Many climbers are so pliant that with proper care they can be trained almost at will, and the form of the pergola can either be defined or a massed effect produced where the composition of a picture so requires.

Every pergola has some individuality of its own, but its first duty is to play its part in the larger views of the garden. If it can simultaneously secure some good side effects in conjunction with neighbouring planting details, so much the better. The interior of the pergola belongs to itself, and if happily treated will quite dispose of the fallacy that a pergola is only worth looking at from the outside.

The desire for great masses of colour is rather overdue. I think it is a mistake when a pergola occupies a prominent position to

I remember an instance in a Devonshire garden where a sturdy Fuchsia was growing on a pier and looked as if it had strayed from a large adjoining group of these shrubs to shake hands with the pergola. Through the arches of the latter one saw a bank of Heather sloping to the foot of the piers. The pergola was planted almost entirely with claret-leaved vine and reddish-purple Clematis. A pink Rose or two and the large mass of Fuchsias close by gave the whole thing a very warm and comfortable effect.

It is scarcely necessary for me to enumerate the many plants which are so often recommended. The most favoured are perhaps the varieties of vine, Roses, Clematis, and Wistaria.

Vines are most useful when shade is required for its own sake, and everyone knows the beauty

of the autumn tints of such species as *Vitis Thunbergii*, *Coignetiae*, *Henryi*, and others. *Clematis* is, I think, almost my favourite plant for pergolas. The more rampant species, such as *montana*, *flammula*, and *vitifolia* are such honest hard workers and the habit is so graceful. Other beautiful sorts are insufficiently used. I give below a selection kindly furnished me by Mr. A. Jackman.

Roses for the pergola have already furnished material for many a chapter, and I need not enter upon this big subject. I give a list of Roses Mr. G. Paul is good enough to recommend.

The *Wistaria* at its best is unbeatable. The graceful foliage, beautiful flowers, vigorous growth, and picturesque stems, make it perhaps the most striking of all plants for a pergola.

An unusual advantage of the *Wistaria* is that the interior of a pergola gets the benefit of a good share of the blossom. The white-flowering varieties show up extremely well, and a combination of mauve *Wistaria* and *Laburnum* is very effective. The vigour of *Wistaria* is astonishing. There was, and no doubt still is, at Cold East, in Hampshire, a great plant entirely monopolising a pergola crossing the whole width of the kitchen garden.

Fragrance must not be forgotten, nor the virtues of *Honeysuckle* and *Jessamine* in this respect.

I conclude with a reminder concerning fruit trees for pergolas, and give below a list of Apple and Pear trees recommended by Mr. Allgrove as most suitable:—

FRUIT TREES FOR PERGOLAS.

Desert Apples.

Beauty of Bath.	Cox's Orange Pippin
Langley Pippin.	Adam's Pearmain
James Grieve.	Albington Pippin.
Lady Sudeley.	Wesley.
Worcester Pearmain.	King of the Pippins.
Christmas Pearmain	Fearn's Pippin.
Cooking Apples, possessing size, colour, and Quality.	The Queen.
Empress Alexander.	Lord Derby.
Bismarck.	Warner's King.
Colombi Pippin	Newton Wonder.
Cox's Pomona.	Bramley's Seedling
Lane's Prince Albert.	Rev. W. Walks.
Peasegood's Nonesuch.	

Pears.

Williams' Bon Christian	Maria Louise.
Clapp's Favourite.	Pitaston Duchess.
Marguerite Marriault.	American's.
Louise Bonne of Jersey.	Dominé du Comice.
Conference.	Emile d'Rey.
Triomphe de Vienne.	

ROSES FOR PERGOLAS.

Autumn-Flowering Noisettes.

Alistair Stella Gray.	Mrs. Cochet
Aimée Vibert.	Réve d'Or.

Hybrid Noisettes.

Paul's Single White	Zephyrin Drouin.
---------------------	------------------

Climbing Hybrid Perpetuals

Climbing Fran Karl	Climbing Rodolamachi
Druschki.	

Climbing Hybrid Teas.

Climbing Richmond.	Climbing Mrs. W. G.
Climbing Caroline Testout.	Grant.
Climbing La France.	

Cluster Roses, Wichuriana's, &c.	
Shower of Gold.	François Guillot.
Paul Transon.	Gerbe Rose.
Albéric Barbier.	Paradis.
François Jumeville.	American Pillar.
René André.	Tox Rambler.
Louisa Gertraise.	Bush Rambler

For Foliage, Single Flowers, rubrifolia.	Brunonis.
Reine Olga de Wurtemberg.	Himalayensis.

CLEMATIS RECOMMENDED BY MR. A. JACKMAN.	
Spring—	
Miss Bateman.	Sir Garnet Wolseley
The Queen.	Robert Harbary.

Summer—

Beauty of Worcester.	Lord Neville.
Fair Queen.	Maria Brisseler.
Henry.	Mrs. Hope.
Lady C. Neville	Nelly Moser.

Autumn—

Comtesse de Bouchard.	Mrs. Cholmondeley
Gipsy Queen.	Star of India
Jackmanii	Ville de Lyon.

Small-Flowered—

montana rubra.	Admiration.
montana superba.	Comtesse of Onslow.
<i>Vitisella albo variegata</i>	Duchess of Albany
<i>V. Kerriouana.</i>	

LETTERS FROM SOLDIER-GARDENERS.

GOOD GARDEN PLANTS IN GREECE.

I AM writing a few notes which may be of interest to the readers of your old and esteemed paper, of which I was a constant reader for twenty years before joining the Army. Before leaving England I was head gardener to His Grace the Duke of Wellington, at Ewhurst Park, Basingstoke, Hampshire, and a member of the Royal Horticultural Society. Some of the plants I have noticed in Macedonia are well known in good gardens in England. The Snake's Head Lily, *Fritillaria Meleagris*, which is found in the Water Meadows at Swallowfield always under water, may be seen here on dry banks facing south, and flowering magnificently; again, *Cyclamen Comm.* at the time of writing, is flowering in thousands on the slopes of a dry nullah facing south-west. This, to my mind, is the prettiest sight in the Balkans, and worthy of a visit from anyone in peace time. Other things growing in luxuriance are *Heliotropes*, *Salvia nemorosa*, *Salvia Pneumonanthe*, *Clematis recta*, a lovely blue *Phlox* of the *decussata* type, *Faturas*, the annual white and violet-coloured varieties; *Linum flavum*, *Hypericum*, *Dianthus barbatus*, *Achusa italica*, and the *Dryopteris* variety, which provides a sheet of blue for miles; *Linum marbonense*, which is met everywhere, and amongst the rocks by the Vardar River *Lilium caudense* is to be seen in abundance, whilst the spathes of *L. palestinum* show purple and black all along the valleys. *Celsia cretica* and *C. arcturus* make fine sights carpeted with *Anagallis*, *Ajugas*, *Ceraniums*, with the Alpine Strawberry make a riot of colours. A lovely sight in the spring is *Anemone peninina*, also *Jasminum nudiflorum*, and *Myosotis palustris*. Christmas-Roses abound, also *Cypripedium* spectabile and a perennial Pea a foot in height, which I do not know, is a mass of flowers. Poppies have a splendid effect as they are cultivated in fields; *Muscari*, *Omphalodes*, *Leontopodium*, *Oenothera*, and *Scabious* are found everywhere; *Verbena venusta* grows to perfection, and *Erigonum* in variety. Peppermint in the nullahs stands 3 feet high, and the scent is very pungent. A gem is a small *Aconitum* 12 inches high and of a lovely shade of violet. *Gypsophila* with white and pink flowers are fairly common; the old-fashioned *Clary* (*Salvia Sclarea*), *Rodanthus*, and *Moring* Glory lend a beautiful touch of colour to this remarkable country. One thing noticeable is the absence of bees and wasps, and the flowers have but little or no perfume. Fruit exists in variety. Of the Mulberry, the white variety is grown largely. The system of growing the Mulberry is entirely different from that practised in Britain, as the natives grow and fruit the trees on the cut-back principle, the fruit being all produced on the young wood, similar to our own Cob and Filbert Nuts. I am in a convalescent camp at present. I expect to take up gardening again when I return home. All good wishes for the good old *Chronicle*; I hope soon to be reading its notes again. *Pte. M. Dorsett, Salonica Forces, Greece.*

FAMILIAR FLOWERS IN THE BALKANS.

It may be of some interest to *Chronicle* readers to record the fact that many of our most useful herbaceous and Alpine plants grow and thrive in a wild state out here. Also, there are various dwarf-growing plants to be found, principally on the sides of the ravines among the foothills, which, in my opinion, if they could be successfully grown in England, would be of great value in the rock or woodland garden. Of the latter, one which has impressed me is a low-growing, glaucous foliaged deciduous shrub bearing large, pale-mauve flowers, somewhat similar in shape to the well-known *Helleborus niger*; it thrives in hard, sandy soil, and appears to revel in drought and sunshine. Another and smaller plant, bearing small

racemes of sweetly-scented flowers, reminds me much of a miniature *Genista*, while a second yellow-flowered Alpine resembles a *Mesembryanthemum* more than anything else, while yet another, bearing large, deep-blue inflorescences, appears to be closely allied to the *Gentian* family.

Among the well-known English flowers to be seen in a wild state, I have noticed on several occasions, usually on or near the sea-shore, well-flowered clumps of *Statice latifolia*, a somewhat coarse type of *Myosotis*, fine specimens of *Galega officinalis*, and more than one variety of the shrubby *Veronicas*.

One notices quantities of *Eryngium*, mostly *E. glaucum*, though I have also seen isolated specimens of *E. amethystinum*, and there is also a very large and handsome *Thistle*, which I have been unable to identify.

In swampy places one finds another very ornamental plant, not unlike a small *Buddleia variabilis*, either in flower or foliage, but this also I cannot fit a name to thus far.

Early in the year there were any number of *Crocus* flowers to be found on the hills, in every shade of colour, but with little or no foliage, and I have also, on more than one occasion, found clumps of a miniature *Hyacinthus*, presumably a forerunner of the familiar *H. Muscari* of the woodland gardens at home.

When I first came out here, more than a year ago, I thought this a singularly uninteresting country from a horticulturist's point of view, but since passing through the growing season, which extends roughly from January to May, I have changed my opinion, and were the distance only less, or the transport quicker, I should certainly be tempted to try my luck with some members of the flora of Macedonia at home in England, in those longed for days "after the war." *G. E. Palmer, Lt.-Col., R.L.M.C. (formerly of Tilstone Gardens, Turpoley, Cheshire).*

THE KITCHEN GARDEN.

By J. DESS, Foreman, Royal Gardens, Windsor

FRENCH BEANS.—Plants of French Beans which are growing in slightly heated pits should be given the benefit of a free circulation of air in sunny weather. Maintain the temperature at 55°. Examine the roots, and if the soil is dry give one good soaking with weak liquid manure. Syringe the foliage only when the weather is mild and bright, as the plants are more liable to be injured by damp than those grown in pots in a warmer house or pit. If pods are in demand during the winter make sowings in 7-inch pots every eight days to maintain the supply. Crock the pots carefully and use light, rich soil, which should be pressed moderately firm. Place 6 or 7 seeds in each pot and cover them with 1 inch of the finest soil. Apply water sparingly until the young plants are 2 inches high, when more moisture is necessary. A temperature of 60° is suitable. Syringe the foliage lightly on fine, sunny days. As growth advances the plants must be kept upright, and there is no better means of supporting them than a few small twigs placed in each pot.

ASPARAGUS.—The beds should be divested of all decaying foliage, the surface soil broken lightly with a fork, and a dressing of decayed horse-manure applied if necessary. Some of the surface soil may be carefully removed before the manure is applied. The alleys may then be dug up as roughly as possible to expose the soil to the frost and weather.

GLOBE ARTICHOKES.—The plants should be afforded protection by placing a quantity of straw around the clumps. Leave the centre of the plants open and exposed to the light, or decay may result. The soil between the rows

should be dug, and, if sharp frosts occur, a few inches of long manure may be spread over the surface.

RHUBARS.—Suitable roots should be dug up and exposed to the weather for a fortnight before placing them in warmth. Crowns which have been in their present position for two or three years are large enough for forcing, which may be done in a Mushroom-house or other building having a temperature of 55°. At Frogmore we use a slightly heated pit for the purpose and place the roots on a very gentle hobbed, which is composed of leaves trodden tightly together and covered with a few inches of rich soil. The roots should be placed as closely together as possible, and the space between them filled with finely sifted soil. Daw's Champion is a suitable variety for early forcing.

CAULIFLOWER.—Plants of Cauliflowers in the open garden should be examined at least twice weekly, as a few degrees of frost may soon ruin a valuable crop if protection is not afforded to all heads which are formed, but not of sufficient size for cutting. Protection from a few degrees of frost may be afforded by placing a few spare green leaves over the crown and drawing the outer leaves up in such a manner as to protect the crown until it is ready for cutting. When the season is further advanced and more protection is necessary the plants which have formed small crowns should be lifted carefully with a good ball of soil to each and placed close together in trenches, which should be made as the plants are placed in position. The stems of the plants should be placed deeply in the soil as the work of digging the trenches proceeds. The plants should be divested of all decaying leaves as they are lifted, and placed in convenient batches quite close together, where they may be protected by spare lights and covered with fern or other dry material in case of severe frosts.

THE HARDY FRUIT GARDEN

By W. A. COOK, Gardener to the Hon. Arthur J. DAVY, Abbots Wood, G. Halming, Surrey.

PLANTING GOOSEBERRY BUSHES. It is a suitable time to plant Gooseberry bushes. The ground should be dug deeply or trenched, plenty of lime incorporated with it, and if the soil is light in texture and poor in quantity, a little bone meal employed. The plants should possess fairly long stems to keep the branches clear of the ground. A few desirer varieties should be grown as double or triple cordons, training them to four strands of wire stretched across the plot. The first wire should be a foot and the top one 6 feet from the ground level, with two intermediate ones. The main or outside post must be firmly set, to keep the wires in position. In a short time the stems will reach the top wire, and subsequently bear heavy crops on spurs. By this system of training the fruits are easily protected and gathered, whilst cordoned trees are quick in giving good returns, especially when trained to tall stakes. Place one stake in the centre and one at each corner of a square 2 feet or 3 feet wide if a cross-growing variety. The following is a list of select varieties: Langley Beauty, yellow; Langley Gate, white; Yellow Champagne, Whinham's Industry, Dan's Mistake, Whitesmith, Crown Bob, Keepsake, Trumpeter, and Pittsnot Green-gage.

PEACH AND NECTARINE TREES. Proceed with the planting of Peach and Nectarine trees in the soil that has been prepared for their reception. If young trees are to take the place of old ones it will be advisable to plant them in whole or at least one half of fresh soil. The best soil is moderately heavy loam which has been stacked for at least six months. Loam freshly cut from good pasture land can be used as a bottom layer, turning the grass side downwards. A small quantity of half-inch bones and some rubble should be mixed with the soil that the roots are actually planted in. If the trees are to be trained against south walls they should be planted about 18 feet apart, one at every 9 feet. Later the trees may be thinned, and those removed used for fur-

nishing Peach houses. In this way good trees are always available for planting. Trees that were not pruned last season will be in a suitable condition for removing, and, if carefully moved, should bear crops next season. In moving trees of this kind take a trench deep and wide enough for the operator to work right under the ball of roots, when it can be lifted out on a strong mat and the tree taken away. Make the soil firm as planting proceeds by continual ramming around the roots. Firm planting results in short-jointed growth of a firm texture. Should the soil be dry give it a heavy soaking before planting the tree, or the soil will break away, destroying many roots. Good varieties of Peaches for outside culture are Waterloo, Hale's Early, Goshawk, Grosse Mignonne, Hy-mond, Peregrine, Stirling Castle, Barrington, and Sea Eagle. This selection will furnish ripe fruits from the middle of July to the end of October. Nectarines Rivers' Early, Cardinal, Lord Napier, Pine Apple and Humboldt are all excellent sorts.

FRUITS UNDER GLASS.

By JES. HUNSON, Head Gardener at Gunnersbury House, Acton, W.

STRAWBERRIES IN POTS.—Strawberries in pots have made good weather. Runners were not very plentiful this season in some localities, the reason for which seems to be somewhat obscure. Because of this shortage many growers were late in potting their stock. Late plants should be placed in cold frames, and the lights kept on except in dry, sunny weather. I prefer to store the plants in frames, but this is not always convenient. The next best plan is to arrange them closely on the flat and cover the pots with ashes. See that the drainage is clear. Pull out all weeds and remove small runners that may have developed, but do not take off any leaves.

LATE PLUMS IN POTS. Late Plums have furnished useful fruits during the past six weeks or more, and I still have fruits of Cox's Golden Drop, and its red variety, Tokeworth Imperatrice. These late Plums have been gathered for about three weeks and kept in a dry room.

LATE FIGS. Our late Figs in pots are dropping their leaves freely, and as the crop, which has been a most abundant one, is practically over, we shall now stand the plants more closely together. The temperature will be reduced to the normal for the winter, but we shall safeguard the plants from frost. The amount of water at the roots should be reduced gradually, but never entirely withheld. Figs are most accommodating as to the room they require in the resting season. The plants at Gunnersbury House are often stood out to rot, and in this way more room is available for other pot plants during the next few months. To destroy brown scale we dress the back of each tree on with liquid Fishers Compound. This needs to be done down to the soil level. Where scale is present collect the leaves as they fall and burn them.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH CORRY, Bart. Carlton Park, Belgate.

CYMBIDIUM.—Plants of C. Lowianum, C. Tracvanum, and many of their fine hybrids, are developing flower spikes, and should be well supplied with water at the roots, whilst others that are backward in this respect should still be kept on the dry side, otherwise new growth will commence and the plants fail to bloom. C. grandiflorum has also finished its growth, and flower spikes are developing from the pseudo-bulbs of the previous year. To ensure success in flowering this species, the plants should be placed in a cool, light position, and the roots kept on the dry side during the winter.

WATERING.—This is always an important factor in Orchid culture, and especially at this season. Plants that have finished their growth should be allowed to dry out between each application of water at the roots, giving them just enough to keep the pseudo-bulbs in a plump and rigid condition. Plants that are growing and others that are pushing up their flower-scapes should be afforded more frequent supplies.

THE FLOWER GARDEN.

By W. J. GUISSE, Gardener to Mrs. DEMPISTER, Keele Hall, Staffs-shire.

PLANTING ROSES.—The soil in which Roses are planted should be well drained. The most suitable soil is a deep, rich loam of a greasy, retentive nature, and, as the trees usually occupy the ground for a number of years, it should be prepared thoroughly. Light soils may be improved by the addition of stiff loam, or, better still, old turf that has been cut and stacked for some considerable time. Loose, sandy soil is unsuitable. In choosing the site, select an open situation, sheltered from cold winds, but not close to large trees or shrubs, the roots of which would exhaust the soil. Trench the ground at least 18 in. in depth, incorporating with it a heavy dressing of well-rotted manure. The soil should be allowed to settle to its former level before planting. See that the roots are spread out to their fullest extent, and trim with a sharp knife any that are damaged. The point of union between stock and scion should be placed just below the surface of the soil. Plant firmly. The following hybrid-perpetual varieties are suitable for planting singly in beds:—Fran Karl Druschki (white), Mrs. J. Laing (pink), Hugh Dickson (crimson), A. K. Williams (crimson red), Louis Van Houtte (deep maroon), and Her Majesty (bright rose). Good hybrid Teas suitable for the same purpose are:—Mme. A. Chatenay, Antoine Rivoire, Caroline Testout, Madame Ravary, William Shann, Gustave Regis, Liberty, Lady Ashton, Sunburst, Dorothy Page Roberts, and Mme. M. Souperet.

DAHLIAS AND OBELIA CARDINALIS.—In lifting Dahlias do not damage the tubers. The roots should be kept in a plump condition, and not dried off too quickly. Label each variety and place the roots in a cool house under the stage or in a cold frame to complete the drying before storing them in a cool, dry, frost-proof shed for the winter. *Obelia cardinalis*, lifted, and planted in boxes filled with a sandy compost, will winter quite safely in a cool frame, provided extra protection is given during frosty weather. Admit air to the frames on all favourable occasions.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to Lady NORTHCOLE, Eastwell Park, Kent.

SALVIA. *Salvia splendens grandiflora* is far superior to the ordinary variety. Whether the plants have been grown entirely in pots, or planted out in prepared borders, and afterwards lifted and potted, matters very little. They do exceedingly well either way. Grow them in a light house or pit, and let them have plenty of space to make sturdy, sturdy specimens. *S. azurea grandiflora* (syn. Pitcher) is another excellent perennial for pot culture, and is at its best in the early autumn. The elegant spikes of azure-blue flowers are very ornamental, and when used with a white or pale yellow ground work, shows to good effect. The plants need plenty of water, and those developing their flower spikes should be given weak manure water. Plants of later blooming species, such as *S. rutilans*, *S. Bethellii*, and *S. gesneriflora*, may be left in the cold frame for the present, the damp bottom being much more conducive to healthy foliage than dry stages. If of necessity they are growing on a dry stage, give the plants a good syringing on bright days.

GREENHOUSE CLIMBERS. Reduce the growth of indoor climbers, according to the requirements of each individual plant. Certain climbers, such as *Cobaea scandens*, *Passiflora*, *Dignonia*, *Tacsonia* and *Mandevilla sycoculosa*, are rampant growers, and need to be kept within bounds. Other climbers, including *Plumbago capensis*, *Swainsonia*, *Habrothamnus* and *Streptosolen Jamesonii*, do not need such severe thinning, but all superfluous growths that have finished flowering should be removed. When the work of thinning and tying is completed, thoroughly wash the plants before rearranging the house. Fumigate the house on an evening or two afterwards. Reduce the amount of water at the roots, but do not withhold moisture entirely.

EDITORIAL NOTICE.

Editors and Publisher.—Our correspondents would oblige by delaying in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to general matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors any notices of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41 Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 33.5.

ACTUAL TEMPERATURE:—Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London. Thursday, November 8, 1917. Bar. 29.4; temp. 45°. Weather—Dull.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—Bulbs at 67 and 68, Cheap-side, at 1 o'clock, by Protheroe & Morris.

The Breaking up of Grass Land.

Everyone in this country who takes the trouble to be conversant with public events is aware that great efforts are being made to encourage the breaking up of grass land. But not everyone, even among those who have been most vocal in opposing this policy, has understood the reason why it has been urged. That reason may be starkly stated as dire necessity. There is a shortage in the world's supply of food. It is common knowledge, moreover, that the tonnage of the world is not equal to all the carrying tasks which are required of it, and that if tonnage has to be used for the carriage of food it cannot be used for other things which, from the point of view of the successful prosecution of the war, are no less essential than food. To give but one example of many which might be given. Fertilisers are essential to production, and not all fertilisers are made at home. Some must be imported. A cargo of an indispensable fertiliser means a much larger potential addition to our food supply than that which would be obtained if Wheat were carried instead of the fertiliser.

Hence the determination of this country to grow more food. Nothing is more vital to the security of the nation. This is not open to question—it is a fact, one of the fundamental and dominating facts of the present situation. It is the plain duty of every man who possesses ground capable of producing food crops to put them to this use. Every yard of garden ground avail-

able should be used for this purpose, and every man capable of working on the land and possessed of leisure should see that he does all that his time and strength allow to produce more food.

But when all this is done, though, as this year has shown, it is no negligible contribution to the food supply, a great task remains for the farmer to perform. There are two courses open to the farmer, and both need to be followed. The one consists in getting the largest production from his existing arable land; the other consists in utilising the great reserve of fertility which exists in his grass land. As is pointed out by Mr. Middleton, Deputy Director-General of the Food Production Department, in his most able report on the breaking up of grass land,* the first of these courses cannot possibly be sufficient to meet and surmount the present shortage of food. The resources of the farmer in labour and in fertilisers are less than in peace time, and high farming requires plenty of labour and large and varied supplies of fertilisers. Hence, although there are farms not a few which might be made to produce more, it is not merely by increasing the production from existing arable land that the necessary increase of food can be made.

There remains, therefore, one resource, and one only—the bringing of more land under arable cultivation. Of land available for this purpose and capable of giving good returns, there is only that now under grass.

After having demonstrated the fact that the food shortage can only be met by this means, Mr. Middleton proceeds to consider the question: "How the grass which must be broken up must be dealt with."

With the object of assisting those engaged in converting grass land into arable the Food Production Department addressed inquiries to a large number of farmers who have gained experience in this work during the past season.

Over 300 replies were received from 55 counties. The replies demonstrate that the results which have been secured this year are satisfactory. Of crops which were mentioned as having given satisfaction are Oats, Wheat, Barley, Peas, Beans, Potatoes, Mangolds, Turnips, and others. The experience gained in 1917 demonstrates conclusively that it is possible to add largely to the food supply by converting pasture into arable.

There were failures, chiefly in the South and East, but elsewhere failures were rare. In most cases the failure was attributed to wireworm, but in not a few cases this noxious pest was not the cause of the failure attributed to it. Damage ascribed to wireworm was often due to the drying out of the newly ploughed land—much was ploughed in the New Year between mid-February and the end of April. In the South the frit fly caused a considerable part of the damage.

Wireworm does most damage in loose, open soils; in a firm soil plants, even

though attacked, have a good chance of re-establishing themselves.

The report considers carefully the time suitable for ploughing, whilst recognising that weather and labour often leave little choice. Poor, heavy clay land in dry districts should be broken in summer, to allow of a partial fallow.

In the case of medium or light land infested with wireworm, many farmers found that Oats did better on late-ploughed and late-sown land than on land broken earlier. Thus in light soils in the South, March ploughing gave better results than December ploughing.

In all cases a firm seed-bed is important. The roller is useful not only for this, but also for checking wireworm. Whereas good pasture land should produce good crops without the aid of fertilisers, it was found that in many clay soils in the South and East which had "tumbled down" to grass a generation ago, had already at that time become exhausted of phosphates. In such soils dressings of superphosphate 2.3 cwt., or of basic slag, are beneficial. For Oats on poor, matted turf sulphate of ammonia and superphosphate are recommended.

The Report, which should be read in its entirety, concludes with advice as to the mode of treatment of different types of soil, and with summaries of the replies received from farmers to the inquiries addressed to them by the Food Production Department.

A GIANT POTATO.—A Potato grown on the farm of the King's Royal Rifle Corps at Sheerness, when lifted weighed nearly 4 lbs. 12 ozs., with a length of 11 inches and a girth of 15½ inches. The tuber was of good shape and normal in every respect, excepting size and weight.

NEW SCOTTISH SEED TRADE ASSOCIATION.—A meeting of the representatives of the seed trade of Scotland was held in the Corn Exchange, Edinburgh, on October 31, to consider the position of the trade as affected by Government orders. Mr. D. BELL, of Messrs. BELL AND BIEBERSTEDT, Leith, presided. The business was conducted in private, but we understand that it was agreed to form a Seed Trade Association to voice the views of the trade and protect its interests. A committee of seven members was appointed to approach the Government should it become necessary. The question of guarantee is one of importance at present, and the general feeling of the meeting was to the effect that, while standards of purity and germination were likely to be valuable, the time was inopportune for giving effect to new regulations for securing them.

THE GENUS EUCALYPTUS.—The first part of the fourth volume of MAIDEN'S *Critical Revision of the Genus Eucalyptus* is devoted to *E. tereticornis*, Smith, and its allies *E. Bancroftii*, Maiden, and *E. amplifolia*, Naudin. *E. tereticornis* is a very complex and variable species, but on this point MAIDEN says: "In a few years I confidently expect that the determination of a species of *Eucalyptus* from a twig of juvenile foliage will present no difficulty." Perhaps not, with the author's complete state of saturation in *Eucalyptus*, but how about others who have not so intimate a knowledge of the genus? The three species now described and figured belong to a group having long, narrow flower-buds and small seed-vessels, and they are all restricted to Eastern Australia (one extending to New

* Abstracted in *Journal of Board of Agriculture*, XIV. No. 6, Sept., 1917.

Guinea), ranging from Victoria to Queensland. *E. tereticornis* and *E. amplifolia* have both been in cultivation in the Mediterranean region for many years, and the latter was founded on cultivated specimens some twenty-five years ago. MAIDEN succeeded in matching original specimens with native materials. *E. tereticornis* is one of the very few Eucalypti known to inhabit New Guinea. The number of species hitherto described and figured by MAIDEN is 160, so that we may expect the total to exceed 200.

FRENCH RESERVES OF POTATOS.—*Le Journal* states: "If the crop of Potatos is abundant, notably superior to that of last year, the disease has, nevertheless, caused serious losses. These have been particularly heavy in certain localities. The sites for storing the tubers should be powdered over with quicklime, each layer of tubers of a thickness of 8 to 10 centimetres, must have a fresh sprinkling, and another must be given to the surface of the heap."

POPULAR WOOD TO BE FELLED.—Wythop Woods, at Peil Wyke, stretching for three miles on the western side of Bassenthwaite Lake, one of the most popular tourist resorts in the Lake Country, has been bought by the Government from Sir HENRY VASE's trustees, and is to be felled for its timber, which is largely Oak.

PUBLICATIONS RECEIVED.—*The Small Garden.* By Mary Hampden. (London: Herbert Jenkins.) Price 5s. net.—*The Potatos Order, 1917.* By J. L. Anderson, Solicitor and Town Clerk, Cupar. (Edinburgh: William Hodge and Co.) Price 1s. net.

PLUM ORPINGTON PROLIFIC.

The new late Gage Plum illustrated in fig. 73 has been shown on several occasions this autumn by Mr. H. Close, Orpington, Kent, who obtained the R.H.S. Award of Merit for the variety on October 24, 1916. The fruits in the illustration are reproduced natural size, and it will be seen that they are not so round as in the old Green Gage variety, and slightly smaller. The colour is dull, greenish-yellow, and the appearance generally does not suggest a Plum of high quality, but the flavour is excellent. The variety is one of the latest to ripen, the season being the end of October.

ON INCREASED FOOD PRODUCTION.

POTATOS ON GRASS LAND AT ALDENHAM

MANY are the experiences of growing Potatos on newly ploughed grass land this year, and the majority no doubt have been successful. One of the most successful results that have come under my notice is the fifteen acres of park grass ploughed up at Aldenham House, Elstree. Having seen the plot at various times, I am in a position to note the results, the recording of which may encourage others to do likewise next year. The sward was formerly infested with huge tussocks of grass. These were grubbed up and burned, and the ashes made a valuable stimulant for the Potatos, being scattered in the rows with the sets. In January the plot was ploughed some 5 inches deep, and again cross ploughed, harrowed, and rolled several times, with a view to disintegrating the soil from the turf as much as possible.

Planting was done by the aid of a hauling plough; the rows were 23 inches apart and the sets 15 to 18 inches apart, thus allowing ample space for the development of haulm. The seed was mainly Scotch grown tubers of last year. At planting time five tons of London manure was added to the ashes and garden refuse for the 15

acres and spread in the rows with the seed; a dressing of soot was given before the earthing up was done, but little result of the application of soot was noted, and therefore it will not be repeated. The soil between the rows before earthing was frequently stirred with the hauling plough.

The crop realised some seven tons per acre, the tubers coming out quite clean and singularly free from wireworm. Slugs were slightly troublesome, boring some few of the tubers. There was very little disease, although no spraying carried out. The haulm remained green quite late in the season as compared to some other plots, which may not have received the same cultural attention. The varieties grown were Iron Duke, which was a distinct success in crop, evenness of tuber, cleanness of skin, and, what is important, its undoubted quality when cooked. King Edward was very successful in crop and quality. I saw 5½ tons lifted from barely three quarters of an acre, with only a few diseased tubers. Great Scot was a fair crop; Factor poor. An experiment was tried as to the value of sprouting the seed tubers by boxing as against keeping them in heaps until planting. It was interesting to note the great advantage gained by the sprouting. The growth from these was earlier and stronger, producing a much heavier crop with no disease. The present in-

at a time by placing the finger against the nozzle of an ordinary large syringe, in using which there was no such thing as clogging, as there is when a rose or a self-acting sprayer is used. The Potatos were lifted in the first week of September, when there was not a speck of murrain on the haulms or the tubers, although they were only separated from a badly diseased plot by a narrow walk, and the tubers have remained perfectly sound. No Potatos had been grown on or near the two plots indicated for 15 years, *etc.*, the one where the disease appeared and where it was absent—and the seed in each case was, as far as could be seen, perfectly free from the *Phytophthora*.

My conclusions are that the mixture should be used as soon as it is dissolved, which takes three or four hours; that the first application, in the warmer parts of the kingdom, should be made not later than the middle of June, and if applied at that time and followed up at fortnightly intervals, it is only necessary to spray the upper surfaces of the leaves. That a very fine spray should be applied to every portion of the upper surfaces, only as much being used as will remain on the leaves in the form of dew, for if it runs off, the edges of the leaves are liable to become scorched.

Another time a less quantity of soda will be used. It is found that sulphate of copper dis-

FIG. 73—PLUM ORPINGTON PROLIFIC: A LATE GAGE VARIETY.

tion is to grow Potatos again next year on the same site. After burning the haulm, the land will be deeply ploughed, exposing it to winter rains and frost, with a view to pulverising the fibrous portions. *E. Molyneux.*

SPRAYING POTATOS

So many growers have failed to see any good results from spraying Potatos, some even thinking more harm than good was done, that it is advisable to look into the causes of the failures. In a case immediately under my observation, spraying was commenced in the middle of June, when there was no appearance of disease, and two of the varieties grown, viz., British Queen and Arran Chief, were sprayed five times at intervals of ten or twelve days. The first three sprayings were with prepared mixtures of different brands, bought at the shops, and after the first shower there was very little of the material to be seen. A homemade mixture, consisting of 2 oz. each of sulphate of copper and common soda, was next applied, and although heavy rain fell immediately after the first application, very little of the stuff was washed off. It was found that it was impracticable to spray all the under surfaces of the leaves with the instruments at hand, so, after the first trial, the attempt was given up, and the spraying was done across three or four rows

solved by itself mixes thoroughly with the water and is kept in suspension, but immediately soda or lime is added the sulphate is precipitated, more or less, according to the quantity of the other materials used. The sulphate, of course, is the active ingredient, but used alone at the strength mentioned it burns the leaves. A ½ oz. to the gallon did not scorch the leaves of Runner Beans, but double that strength did scorch them. As the season when this experiment was made was too late for Potatos, I cannot say what the result would be of trying a weak solution of copper by itself, but it seems probable that the soda or lime may have a neutralising effect on the copper, and it would be interesting to know whether exhaustive experiments have been made in this direction.

But why grow late varieties of Potatos where the space is limited, and where it would be an advantage to have succession crops if the ground could be cleared in July? Will some of your correspondents inform me the best early or mid-season varieties to keep through the winter and spring? Good flavour is required quite as much as good appearance, and good habit of growth not more than 13 inches in length. The best flavoured Potato I have tasted this season has been Eclipse, which is a good cropper, but my experience has been very limited. *Wm. Taylor, Bath.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

LINUM PERENNE AND RABBITS.—Some time ago there was brought under my notice an example of the great difficulty which may be experienced in connection with the consideration of what may be called "rabbit-proof" plants. In a certain bay on the Kirkcubrightshire coast there is a wonderfully beautiful "colony" of *Linum perenne*. This is simply fascinating in its season, and gives the portion of the coast on which it grows a feature reminding one of the haze of blue shown in many a woodland and meadow by the flowers of the Bluebell (*Scilla festalis*, or mutants). It has formed one of the prominent features in some of the pictures of a famous Scottish artist, and has elicited many expressions of admiration. But *veronens a nos moutons*. In this bay rabbits abound, yet the Flax is never touched by these pests. A proprietor on the opposite side of the inlet of the Solway, in practically the same conditions, and who is a keen gardener, desired to establish a similar feature on his property, and removed plants and sowed seeds as well. Result—every plant was exterminated by the rabbits! They evidently had discovered that the Flax presented a new edible to them, while the rabbits on the other coast had their appetites cloyed by the plentiful supply. S. ARNOTT.

UTILITY AND ROMANCE OF THE ROWAN.—At p. 155, Sir Isebert Maxwell makes some very pertinent remarks regarding the beauty of the Rowan tree and its golden-fruited variety, but says nothing of the utility of the berries, though it may be well known to him. In the South it is grown solely for ornamental purposes, so far as I can learn; but in the North, many years ago, I enjoyed very much a jelly made from the berries. They were partly boiled, then strained to take out the seeds and skins, sugar was added, and the richly coloured juice still further boiled till it attained the consistency of Red Currant jelly. It was rich in colour and pleasantly acidulated, with a flavour distinct from all other jellies I have ever tasted. The tree grows wild and abundantly on the hills and lower mountains of the Highlands, and is planted in and around gardens further north, where there is no aboriginal arboreal vegetation, and fruits splendidly from the time it gets 6 feet to 10 feet high. There were large trees of the golden-fruited variety, *Pyrus Aucuparia fructu luteo*, around a village garden in Aberdeenshire, in the early sixties of last century, and the naked holes of the trees were so tall that the village boys were never able to raid the trees. They called the berries "Barley Roldans." I presume from the Rowan or Mountain Ash is *Luisroon*, or drink-charm. In 1772, Lightfoot recorded that the Highlanders used to distil a very good spirit from the berries, and that any part of the tree carried about on the person was a sovereign charm against enchantment or witchcraft. I have seen two very old trees planted, one on each side of the approach to an ancient family seat in Kincardineshire, to keep away witches. Their potency, or rather, their want of it for this purpose was well known in the seventies, but out of curiosity the old trees were roned with iron hoops to keep them together, as they were falling to pieces. Just then and for long years previously, many an old house contained a "rantry" or "rante tree" for suspending pots over the fire, though the inhabitants had long lost the knowledge that the word was derived from Rowan tree, and that it was intended to prevent witches from exercising their evil spells in the pot. J. F.

HIBISCUS SYRIACUS (see p. 157).—Unfortunately, in many northern gardens *Hibiscus syriacus* fails to flower, or blooms only occasionally when the seasons are milder than usual. I do, however, know of a few Scottish gardens in which it is a success. I have in my mind's eye one specially good old plant of H. s. Totus albus, which blooms almost every year. It is against a low wall, and partially trained over a slate roof, where it receives the benefit of the heat stored in the stone and slate during the day. J.

SOCIETIES.

ROYAL HORTICULTURAL.

NOVEMBER 6.—The fortnightly meeting in the Drill Hall on Tuesday last gained in importance from the fact that the National Chrysanthemum Society held its annual exhibition in connection with it. Chrysanthemums were by far the most important feature of the show.

Several good groups of Orchids were, however, contributed. Novelties submitted for award gained one First-class Certificate and three Awards of Merit.

The Floral Committee gave four Awards of Merit to Chrysanthemums and five Medals to collections.

There was one important exhibit in the fruit and vegetable section, viz., an exhibit of sixty varieties of hardy fruits, shown by Messrs. H. Cammell and Sons. Several seedling Apples were presented for award, but none received recognition.

At the three o'clock meeting of the Fellows, Mr. E. A. BOWLES delivered an address entitled "Useful Books for an Amateur Gardener's Library."

Floral Committee.

Present: Messrs. H. B. May (chairman), J. Green, J. W. Barr, W. J. Bean, J. F. McLeod, W. H. Morter, C. Dixon, J. Hindson, C. E. Pearson, J. Heal, A. Turner, C. E. Shea, E. F. Hazleton, W. P. Thomson, E. H. Jenkins, T. Stevenson, G. Reuthe, H. Cowley, J. T. Bennett, P. R. Hooper Pearson, E. A. Bowles, and John Jennings.

AWARDS OF MERIT.

Chrysanthemum General Pattern.—A large Japanese variety of a beautiful shade of soft pink as seen from a short distance, but close inspection proves that many of the long, broad florets have a white ground and are faintly mottled and shaded with light purplish pink. The blooms shown were of the largest exhibition size. This variety was exhibited last year under the name of Edward Stanton.

C. Donald.—A Single Chrysanthemum of the Mensa type. The blooms are carried on good stems, and possess three rows of florets. The colour is a deep shade of mauve-rose, with a faint salmon flush. Both these were shown by Messrs. W. WELLS and Co.

C. Crusader.—A medium-sized Japanese variety with particularly substantial and rather broad, short, and stiff florets, which are pure white, with a creamy centre. The stems and foliage are robust, and the bloom remains fresh over an unusually long period, qualities that render the variety valuable for market purposes. Shown by Messrs. LOWE and SHAWYER.

C. Mrs. Hutton.—This new, large Japanese variety is of a rich golden yellow. The florets are narrow, drooping, and graceful, forming an elegant, as well as a large bloom of fine colour. Shown by Messrs. H. J. JONES, LTD.

GROUPS.

The following medals were awarded to collections:—

Silver Flora Medal to Messrs. ALLWOOD BROS., Wivelsfield, for Perpetual-flowering Carnations. A new variety, named Marion Wilson, was shown for the first time. It is a promising flower, of pale buff colour, with distinct stripings of vermillion.

Silver Banksian Medal to Messrs. H. B. MAY and SON, Edmonton, for indoor Ferns and Begonias of the Gloire de Lorraine and large winter-flowering types, of which *Optima*, *Emita*, and *Mrs. Heal* were remarkably good; Mr. G. REUTHE, Keston, Kent, for a varied collection of *Neines*, *Alpinos* and sprays of choice shrubs in flower; Messrs. PETERS, Bayswater, for ornamental shrubs in small pots, some of which were in berry.

Bronze Flora Medal to Messrs. STUART LOW and CO., Bush Hill Park, for Perpetual-flowering Carnations.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart (in the chair), Sir Harry J. Veitch, Jas. O'Brien (hon. secretary), W. Bolton, J. Charlesworth, R. A. Rolfe, J. Wilson Potter, Fred K. Sander, J. E.

Shill, Pantia Ralli, E. R. Ashton, Frederick J. Hanbury, T. Armstrong, S. W. Flory, Gurney Wilson, Stuart Low, Walter Cobb, and R. G. Phwaites.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Astron, The Dell variety (Harrisoniana alba × Dusseldorfiae Undine). Shown by Mr. J. E. SHILL, The Dell Gardens, Englefield Green. The plant bore a fine spike of six pure white flowers with sulphur-yellow disc to the lip. The original form was given an Award of Merit on November 3, 1914. The present variety has rather larger and better shaped flowers.

AWARDS OF MERIT.

Sophro-Laetia Cattleya Bryndir (S.-L.-C. Sandhage × L.-C. Golden Oriole), from Dr. MIGUEL LACROZE, Bryndir, Reohampton. A fine hybrid of good size and very rich colour; the size and form of the flower are derived from the several large-flowered *Cattleyas* in its composition. The sepals and petals are deep port-wine colour or dark ruby-red with a slight gold tint, and small, pure white bases to the mid-ribs. The lip is dark claret-red with gold veining extending from the base to the orange-coloured centre.

Brasso-Cattleya Dietrichiana, Ansaldo's variety (B.-C. Mrs. J. Leemann × C. Fabia), from J. ANSALDO, Esq., Rose Bank, Mumbles, Glamorganshire. A noble flower of large size and with an extraordinarily large lip; the sepals and petals are cream colour tinged with lilac; the lip is much crimped and fringed, coloured bright rose lilac in front, the centre being chrome-yellow with yellow lines extending to the base.

Miltonia Venus var. Fascinator (vexillaria × Phalenopsis), from Messrs. CHARLESWORTH and Co., Haywards Heath. *M. vexillaria* was the seed-parent, and the hybrid is nearest to that species in form and general characters. The flowers are tinged with rose colour, the lip having a greenish-yellow base, from which radiate numerous spotted lines of dark crimson colour.

GROUPS.

Sir JEREMIAH COLMAN, Bart., Gatton Park (gr. Mr. Collier), showed a fine plant of *Cattleya Portia Lorna Fielden*, raised at Gatton, with a spike of nine flowers. These flowers are equal to the best form of *C. Portia*, but with the lateral sepals broadened, deflected, and joined at the bases, each showing the purple colouring of the lip. *C. labiata Lorna Fielden* also showed traces of the lip on the lower sepals, and most of the batch of *C. Portia* of this cross which have yet flowered show the same peculiarity; *Odontoglossum splendens* album, with pure white flowers, following the albinos from which it was raised; a good hybrid *Odontoglossum*, and *Cattleya Gatton Ruby* (*Amabilis × Hardyana*) were included in the group.

Dr. MIGUEL LACROZE, Reohampton, exhibited the very handsome and finely coloured *Cattleya Titrus* var. *Bryndir* (*Octave Doix × Enid*), with four flowers on a spike.

Mr. J. E. SHILL, The Dell Gardens, Egham, showed flowers of *Laetia Cattleya Sunbeam* (C. Maggie Raphael alba × L.C. yellow hybrid), with bright yellow flowers and ruby-red lip with orange centre; and L.-C. Hardybel (C. Hardyana × L.-C. Sevilla).

Messrs. ARMSTRONG and BROWN, Orchidhurst, Tunbridge Wells, were awarded a Silver Flora Medal for a group, in which were several very handsome seedling *Odontoglossums*. Among *Laetia-Cattleyas* was L.-C. Pathan var. *Domitian* (L.-C. *Dominiana* × C. *Dowiana aurea*), a very handsome and finely coloured flower. The new *Cattleya Archimedes* (*Armstrongiae* × *Fabia*), a compact and good flower; *Sophro-Cattleya Atalanta* (S.-C. *Ariadne* × C. *Fabia*), rose red flowers with a golden tint and ruby-purple lip; *Cattleya Dowiana aurea albens*, an interesting, imported form, and the first, probably, with nearly white sepals and petals, were shown well.

Messrs. CHARLESWORTH and Co., Haywards Heath, were awarded a Silver Banksian Medal for a group composed principally of varieties of *Cattleya Dowiana aurea*.

Messrs. SANDERS, St. Albans, were awarded a Silver Banks Medal for a group in which the best novelties were *Cattleya Una* (Lord Rothschild × Cooksonii), the large milk-white flowers having a slight lavender tint, and lilac-marked lip; *L.-C. Flame* (*L.-C. Elektra* × *C. Dowiana aurea*), yellow with a rose tint, and claret-coloured lip; and *Cypripedium Stadium* (Dreadnought × *Ville de Paris*).

Mr. C. F. WALTERS, Deanlouis Nurseries, Balcombe, showed an effective group of *Cattleyas* and *Laelio-Cattleyas*, for which a Silver Banksian Medal was awarded.

Messrs. STUART LOW and Co., Jarvisbrook, Sussex, showed *Cattleya Baron Delbecq* (*Pittiana* × *Dowiana aurea*), yellow with purple markings on the lip, which is shaped like *C. Pittiana*, and showing the *C. granubsea* in that hybrid; and *Cattleya armadillovilliersensis* grando.

Fruit and Vegetable Committee.

Present: Messrs. W. Pountney (in the chair), E. Beckett, Owen Thomas, W. H. Invers, W. Bates, A. W. Metcalfe, W. Pope, F. Jordan, J. Harrison, W. Wilks, A. Ballock, E. A. Banyard, and A. R. Allan.

A *Silver-gilt Knightian Medal* was an odd lot to Messrs. H. CANNELL and SONS, Eynsford, Kent, for a splendid exhibit of Apples, comprising sixty distinct varieties, together with a few Pears. The Apples were of fine size, and the colour was particularly well developed. A place of honour was given to immense fruits of Peasgood's Nonesuch, and other well-known culinary sorts were Lord Derby, Bramley's Seedling, Norfolk Beauty, and Edward VII., the last a solid, late-keeping variety of the Anna-Elizabeth type. There were choice fruits of Cox's Orange Pippin, Adams's Pearmain, Smart's Prince Arthur, Mother, Compton, Allington Pippin, Tom Putt, Hoary Morning, and Ribbury. This last is an attractive, round, red-skinned variety, of medium size.

The ALLIANCE VEGETABLE Co. was awarded a Silver Knightian Medal for desiccated Potatoes shown in the form of meal.

NATIONAL CHRYSANTHEMUM.

NOVEMBER 6. — It was only to be expected that the annual show of the National Chrysanthemum Socy, which was held last Tuesday in the London Scottish Drill Hall, in conjunction with the fortnightly meeting of the R.H.S., should be of less importance than usual. It was therefore all the more gratifying to note that the majority of the classes were represented by exhibits, and taking the quality generally, it was of good average standard. The schedule was reduced to 29 classes, divided into three sections, viz. Open Classes, Decorative Classes, and Amateurs' Classes. There was no entry in the class for 36 Japanese blooms distinct, but there were good exhibits in the classes for 24, 12, and six Japanese blooms respectively. Competition was limited in a number of classes to two or three entries.

AWARDS

FIRST CLASS CERTIFICATE

Mrs. Georgy Monro, Leeds. — A Japanese variety of exhibition size, and one which will, in all probability, become popular as a market variety. The flower is graceful, the fairly broad florets drooping regularly a considerable depth. The colour is brilliant crimson, with bronze reverse, and when illuminated by sunshine or bright artificial light it is particularly attractive. Shown by Mr. NORMAN DAVIS.

CARDS OF COMMENDATION.

C. Lustre. — A handsome decorative Japanese variety of suitable size and form for market use. The graceful flowers are borne on long stems, and the twisting of an occasional floret exhibits the golden reverse colour, which enhances the rich chestnut hue of the blooms. Shown by Messrs. H. J. JONES, LEEDS.

C. Alice Harvey (see p. 192).

The Committee expressed a wish to see again the variety Brilliant. It is a Japanese variety of the decorative or market type, with flowers

of medium size and velvety crimson shade with golden-bronze reverse.

COMPETITIVE CLASSES.

Japanese Blooms Shown on Boards. — The President, Lt. Col. Sir Albert Rollit, offered a Silver Cup for the best collection of 24 Japanese blooms distinct. Four competed, and the trophy was won by Mrs. HAMILTON FELLOWS, Tangle Park, Worslesdon, Guilford (gr. W. J. Smith). The blooms were very nice, fresh, and brightly coloured. Notable varieties were Mrs. R. C. Pulling, Mrs. A. E. Tickle, F. Green (fine colour), Louisa Pockett, Mrs. Lloyd Wigg, and H. E. Converse; 2nd, Mr. A. SMITH, Convent Garden, Roehampton, with smaller blooms, of which H. E. Converse and Mrs. Drabble were noteworthy.

The similar class for 24 blooms distinct was one of the best contested; there were six exhibits in all. The 1st Prize was won by W. H. ALLEN, Esq., Broadham House, Bedford (gr. H. Blake-way), with choice blooms of Mrs. Pulling, Mrs. J. Gilson, Bob Pulling, His Majesty, Mrs. Drabble, Miss Elsie Davis, and others; 2nd, the LORD WANDSWORTH INSTITUTION, Long Sutton, Winchfield (gr. L. Barnard), with Mrs. R. LAYFORD, James Stredwick, and Mrs. R. C. Pulling as his best specimens; 2nd, Mrs. HAMILTON FELLOWS.

Mrs. HAMILTON FELLOWS well merited the 1st Prize in the class for a collection of 6 blooms distinct, in which she showed splendid flowers of R. C. Pulling, W. Farmer, Lady Talbot, Mrs. A. E. Tickle, Mrs. H. E. Converse, and Mrs. Jones; 2nd, Mr. W. H. ALLEN (gr. H. Blake-way); 3rd, Mr. A. SMITH.

Blooms Shown in Vases. — These classes showed a very distinct falling off from those of previous years. Only one exhibit was forthcoming in a class for a vase of a white variety; it was shown by Mr. A. SMITH, to whom the 1st Prize was awarded. The variety employed was Queen Mary. For a vase of a yellow variety there were two competitors; the 1st and 2nd Prizes were won by Mr. W. J. SMITH and Mr. W. H. ALLEN respectively, who both showed Mrs. R. C. Pulling.

Incurved varieties. Although the competition in the three classes for incurved blooms was limited to two growers, both showed in a manner worthy of the traditions of these exhibitions. In all three classes the 1st Prize was won by Mrs. CHRYMERS, Furants, Bockley (gr. A. B. Hudd), and the 2nd by H. BRISSETT, Esq. (gr. E. Leave). Both competitors showed much the same varieties, among which were included Edin' Thome white, Clara Wells, J. Wayne, very delicate oak, Godfrey's Eclipse, Calypso, and Master C. Hall.

Pompons and Singles. There was a class for six vases of Pompons in three varieties, and another for six vases of the same shown as sprays without disbanding. F. J. JARROW, Esq., St. John's Wood (gr. A. Robertson), was the only exhibitor in the former class, and was awarded the 1st Prize for admirable specimens of Mrs. Ellis, Dordan, W. Sabey, Prince of Orange, and Black Douglas. Mr. H. RUSCHEMAN, Wandstead, was awarded the 1st Prize for sprays of Pompons.

The exhibits of Single Chrysanthemums were exceedingly meritorious, and Mr. RUSCHEMAN, with a fine collection, carried off the 1st Prize for a display arranged on a table 8 feet by 5 feet. His blooms were not large, but they were of model shape, and very finely coloured. *Jessica* (orange), Orlando (yellow), Monsa (white), Metta (cinnon red), and Mrs. Leo Thompson (lemon yellow), were the best; 2nd, Mrs. CHRYMERS, with larger blooms. This lady exhibited in the class for six vases of flowers of larger varieties, six flowers in each vase.

Affiliated Societies' Class. — The Finchley Chrysanthemum Society showed the only exhibit in the class for twelve vases of cut blooms, representing the Japanese, Incurved, Single, Anemone, and Pompon sections, and was awarded the 1st Prize.

Amateurs' Classes. The LORD WANDSWORTH INSTITUTION was placed 1st for (a) 12 Japanese blooms, distinct, (b) 6 Japanese blooms, distinct, and (c) 6 Japanese blooms, three varieties. The Institution was also placed 2nd in the class for 3 vases of Singles, in which Mr. J. CLAYTON, Addlestone, won the 1st Prize.

Decorative Classes. — The best table, decorated with Chrysanthemums, was arranged by Mr. D. B. CRASE, Wood View, Higgiate. He employed yellow and bronze Singles, with a few sprays of bronze Pompons, relieved by Croton foliage and trails of *Asparagus plumosus*. Mr. JARROW showed the best vase of Single Chrysanthemums and the best vase of Large Exhibition Blooms, and was awarded the 1st Prizes. Mr. CRASE showed the best basket of Chrysanthemums.

Trade Exhibits. — Mr. NORMAN DAVIS was awarded the Gold Medal offered by Messrs. Clay and Son for the best miscellaneous exhibit, also the Society's Silver gilt Medal. His group contained fine blooms of Mrs. Geo. Monro, Junr., Edith Cavell, Mrs. Algernon Davis, and Market Bronze. A Silver Medal was awarded to Messrs. W. WELLS and Co., LTD., Merstham, for a group of Single and decorative varieties.

CROPS AND STOCKS ON THE HOME FARM.

BASIC SLAG ON DOWN LAND.

SOME years ago I carried out experiments with a view to testing the value of basic slag on down grass land. It is generally considered by those who have not tested the matter themselves that basic slag has no beneficial effect on chalky soils, or even where the subsoil is chalk. But I know of no manure that produces such a marked improvement in the quantity and quality of grass, and none that has such a lasting effect, not even farmyard manure.

Five years ago I dressed a portion of the Downs at an altitude of 400 feet, which had previously grown more Thistles than grass. A marked improvement in the colour of the grass was apparent the first season after the application, and the difficulty has been ever since to keep the sheep away from that part when out grazing and exercising.

Even now, although none has been added since, the straight line of colour in the grass is discernible at a mile away. Surely such proof ought to convince the most sceptical of the value of this manure.

The depth of soil is but 3 inches in places before the chalk is reached; in the valleys, of course, it is more. Many who see the increase in growth wonder where the Clover comes from, as none was visible beforehand. I presume this is a question of the seed lying inert in the soil until the constituent is applied that induces germination. When we consider, too, the ease with which basic slag can be applied as compared with the labour involved with farmyard manure, the wonder is it is not used universally. But many apply it too late. They do not sow it until April, and then, because of its slow solvency, it has no time to influence the crop, and the slag is blamed as useless. November is the best month to apply basic slag. The winter rains then aid in washing the particles slowly down to the roots of the grass, the effect being noticeable the first year in the growth of Clovers especially.

Some writers advocate the use of 8 cwt. to 10 cwt. of slag per acre. Personally, I would rather apply this quantity in two dressings, with a two years' interval, as I think 10 cwt. at one application is too much for effective absorption. A second dressing of 4 cwt. at the end of two years would give a further fillip, and would show a marked improvement in the growth, quality, and colour of the grass, making it sweeter for the sheep to browse upon.

When we consider how useful these downs are, their low rent, and how little they are cared for, it would appear that those who neglect them have much to learn.

A thorough scratching of the surface with iron harrows before the slag is applied would aid the proper distribution of the particles. If it were possible to roll the land during the early spring months it would assist in consolidating the grassy surface after harrowing.

While it is possible to sow basic slag by hand in small quantities, it is much more evenly spread by the aid of a distributor. I use one of Ben Reid's basic slag machines, with which any amount per acre can be applied, and being distributed evenly and within a few inches of the

surface, there is no waste from wind. Cattle of any kind should not be allowed to graze the grass for quite three months after the slag is sown, as some time must elapse before the manure disappears.

CATTLE IN THE YARDS.

WITH so much rain and little sun, the grass in the meadows has been for a long time very soft and not nearly so beneficial to the animals as when with drier weather it is more hearty. In the case of young animals of pure-bred Jersey or Guernsey cattle, it is unwise to allow them to remain in the open too long, as they are liable to catch cold, which may develop tuberculosis if neglected; one cannot be too careful in this precaution. In the case of Shorthorns or crosses from Shorthorns, the animals are generally hardier, and may remain outside longer.

If a yard has a meadow attached to it that the animals can run out by day and sleep in the yard at night, the conditions are the best possible. Sweet Oat straw, or rough Hay, will be an advantage even to those animals which have the run of the meadow by day. In the case of those wholly in the yard, Oat straw with Cabbage or Maize will provide a good food. If it were possible to give to the younger animals a few pounds of cotton cake per week they would thrive all the better for such attention. *E. Malynur, Swanmore Park, Bishops Waltham.*

ANSWERS TO CORRESPONDENTS.

APPLES: *J. H. B.* In the Report of the Apple Congress held at Chiswick in 1883, Lady Lennox is described as being a small, flat Apple, streaked with yellow. It ripens late, and is very acid in taste—suitable only for culinary purposes.

BISULPHIDE OF CARBON: *T. B. A. 1.* For treating soils and composts, you might use one ounce for the cubic foot. 2. The soil will not be rendered injurious to plant roots, as the fumes are harmless to the root tissues; the liquid, however, will damage roots that come into direct contact with it. 3. This fumigant may be used for plants in pots in the form of 1 ounce injections, or less for small plants.

CORRECTION.—A First-class Certificate was awarded *Berberis polyantha*, illustrated in the last issue, fig. 70, p. 183—not an Award of Merit, as stated.

CUCUMBERS FOR SEED: *T. G.* Leave the fruits on the plants until they are perfectly ripe, then cut them, split them, and take out the seeds with as much of the pulp as possible. Lay the mass of seeds out on sheets of brown paper to dry; when almost dry, mix with some fine, dry sand, which will absorb the last remaining traces of moisture. Then pass the seeds over a fine sieve, rubbing all the sand and other small refuse through, and leaving on the top the cleaned seeds. Keep in a dry place until required.

ENGAGEMENT OF GARDENERS: *J. B.* Write to the National Service Department, Hotel Windsor, Victoria Street, S.W. 1.

FICUS STIPULATA MINIMA FRUITING: *A. P. N.* Your plant is the variety *F. stipulata minima*. The species has also been named *F. repens* and *F. pumila* in gardens, but the last-named is a different species. *F. minima* is a small-leaved variety of *F. stipulata*. When this species reaches the fruiting or adult stage it produces large leaves of quite a different type from the creeping juvenile stage, just as in the case of the Ivy. Many years ago a plant in the Nymphaea house at the Botanic Gardens, Oxford, reached the adult stage, and a shoot of it was taken off and rooted as a cutting. This was planted out in another house and trained to a wall. In 1890 the cutting had grown to a height of 8 feet to 10 feet, retaining its arborescent character, though it had numerous long branches, and the leathery, netted leaves were almost as large as those of a Camellia. This was the typical form, *F. stipulata*. Your plant, being the variety *F. s. minima*, has smaller leaves in the adult, or fruiting stage. A fruit of the typical form is illustrated in fig. 74. A fruit of *Ficus stipulata* (repens) was shown at a meeting of the Fruit and Vegetable

Committee of the Royal Horticultural Society on October 11, 1898, by Mr. John Williams, Whitbourne Hall Gardens, Worcester. Creeping and fruiting shoots of the typical form were shown at a meeting of the Scientific Committee of the Royal Horticultural Society on October 22, 1912, from Blackheath, Kent, but no fruits.

MUSK MELONS: *D. S.* *Cucurbita moschata*, of Nicholson's *Dictionary of Gardening*, is merely a form of *C. Melo*, of which species the Musk Melons of America and Canada are varieties. Bailey, in the *Standard Book of American Horticulture*, states that the modern cultivated varieties of Musk Melon are supposed to have been derived from the wild types native to Asia and Africa. Cantaloup Melons are certainly more hardy than ordinary English hothouse Melons, and are grown in great numbers in frames by the market gardeners of Paris. The Water-Melon belongs to a different genus, namely, *Citrullus* (*C. vulgaris*), native of Africa. It furnishes one of the important crops of the United States. The value of the crop for one year given in

FIG. 74.—FRUIT OF *FICUS STIPULATA*.

the census returns for 1910 was nearly \$4,500,000. There are six other vegetable crops of even greater value in the States, and we state them in their order of importance: Potatoes, Sweet Potatoes, Tomatoes, Cabbages, Onions, and Sweet Corn. It is not at all likely that the Water-Melon would succeed generally in this country as an outdoor crop.

PEAR LEAVES WITH BLISTERS: *A. S.* *Henteyon-Thames.* The leaves are infested with the Pear Leaf blister mite (*Eriophyes pyri*). Spray with lime sulphite (full strength) in winter, and if necessary with paraffin emulsion in spring or early summer.

PEARS DISEASED: *A. and H.* The Pears are attacked by "scab." Spray the trees with Bordeaux mixture just after the fruit is set, and again three weeks later. Use a fine, misty spray, and take pains to spray the under-sides of the leaves, as it is there where this fungus forms its spores, which infect the fruit.

PLANTS FOR WALL AND ROCKERY: *Mrs. W.* One of the most suitable plants for a wall is the Cheddar Pink (*Dianthus caesius*). You can also use many sorts of Saxifraga, Dianthus,

Sempervivum, Aubrietia, Arabis, Linaria, and Cerastium. The rougher and more rugged the wall the better will the plants establish themselves. For a shady rockery the following will be suitable: Saxifraga granulata, Aster alpinus, Epimedium in variety, Omphalodes verna, Primula acaulis, Anemone alpina, Hepaticas, rose, white and blue, dwarf Irises, and Tharella cordifolia. If sufficiently cool you might try a few hardy ferns, such as Asplenium angustifolium, Lastrea cristata, Polystichum acrostichoides, and Scolopendrium vulgare, or Hart's Tongue.

PROPAGATING RHODODENDRONS: *W. P.* Rhododendrons may be increased by seeds, cuttings, layering, and grafting. By seeds.—These are best sown in early spring in well-drained, peaty soil, in shallow pans or boxes and placed in a warm greenhouse, or they may be sown in frames out-of-doors, taking care to only just cover the seeds with very finely sifted soil, which should be watered through a fine rose water-pot. If hot, dry weather ensues it will be advisable to cover the glass or seed-bed with tiffany or any similar material.

When the seedlings are large enough to handle they should be picked off, and later on transferred to nursery rows out-of-doors. By cuttings.—The best time to take cuttings is just as the wood is getting firm. The cuttings should be made quite firm in the soil, placed in a warm, moist, close case, sprinkled occasionally, and protected from the sun. By layering.—This is very satisfactory, but certain hybrids are rather slow in forming roots. The well-ripened shoots should be tongued (as in Carnations), but in the case of varieties whose wood is very brittle it will be safer to scratch the bark only and then peg into the soil, which should be kept moist. By grafting.—Grafting is practised mostly in the case of hybrids. It is a quick method, but we prefer plants on their own roots. *R. ponticum* and *R. catawbiense* are the species generally used as stocks for the evergreen varieties, and saddle-whip or tongue grafting are the best methods to adopt. The stocks, which should be strong, healthy, 2-3-year-old seedlings, should be semi-established in pots before grafting, which may be carried out any time between October and March. The pots should be plunged in tan or stood in a close case with a temperature of about 60°, taking care to shade on bright days. An occasional syringing overhead is advisable, and after a union is effected air should be admitted and each plant secured to a neat stake to prevent accident.

RAILWAY FARES FOR LAND WORKERS: *M. M. K.* Women enrolled in the Land Army receive free railway passes to the places where they are sent, but occasionally workers are allowed, in certain cases, a rebate on fares by which they can get a return ticket to the place where they are to work for the price of single fare and a quarter. If you are going to work on the land, and wish to avail yourself of such a privilege, you should apply to Miss Tenant, Employment Exchange, Trowbridge, Wilts, giving her all particulars. No reduction is allowed for any other purpose, such as for a holiday.

ECONOMICAL STOKING.

WITH the approach of winter, the subject of the scarcity of fuel of all kinds becomes of increasing interest, not only to householders, but also to those whose duty it is to provide the necessary warmth for delicate and valuable plants in the hot-houses. The problem is how to maintain the maximum of heat with the minimum of fuel; and in this matter the choice of the boiler is of importance. Probably, from this point of view, the tubular horizontal boiler is the best, as it can be used with a shallower stoke-hole than is required for most other kinds. The tubular boiler will burn almost anything—stems of trees, brushwood, and much rubbish which would otherwise be wasted. The boiler should be set on a brickwork bed, with a rise of at least half an inch per foot run, from front to back, where the flow-pipe connecting with the main pipes in the house should be fixed. Thus a horizontal tubular boiler of nine feet in length should have a rise of four and a half inches from the furnace door to the back. Do not allow too much space between the top pipes, or the dome of the boiler, and the fireproof tiles or brick arch covering the boiler—a clear space of four inches is quite enough. The damper for regulating the draught in the chimney should be fixed immediately above the point where the flue enters the chimney. If the furnace house is in the open air, and not too near any trees or buildings, the chimney stack should be from 12 to 15 feet high, so as to ensure a good draught, especially if anthracite coal is the fuel used.

Most readers of the *Gardeners' Chronicle* have more or less experience in stoking, but for the benefit of others who are pressed into work of this kind for the first time a few simple directions will not be out of place. To light the fire, make a small heap of loosely placed paper and shavings, then place over the pyramid some small, and then larger, pieces of wood, interspersed with dry chips, straw or shavings. Over this, lay a quantity of coal and coke broken small, and then light the paper,

etc., in the centre, continually adding coal and coke until a good, glowing fire is steadily burning. Press this burning mass to the back of the furnace bars with the fire hoe, and go on adding fresh fuel until the water in the boiler is at the desired heat. When starting the fire afresh in the morning, draw out the damper to secure a vigorous draught, but when the fire is established it should be pushed back three-quarters of its possible extent. Before applying more fuel, push the clinker bar under the fire the full width of the furnace base, removing any clinkers which may have formed during the previous hour or two, push the fire to the back part of the furnace, and again add more fuel in front. From the early morning onwards the fire should be attended to at short intervals until it is finally banked up at night. Do not open the furnace door in order to maintain a steady heat; this should be done by careful regulation of the damper, the exact working of which can be easily ascertained by careful and intelligent observation. Again, it is a great mistake to put on more fuel than is actually needed to maintain the desired temperature. Such action leads to waste of fuel and overheating, and makes it very difficult to prevent the boilers from boiling over, especially in the case of large installations, intended to heat three or four houses.

In making up the fire for the night, extract the clinkers and add more fuel as described above. In addition to this, when the furnace is half-filled, throw in a few shovelfuls of ashes, then some more coke, then some more ashes, and so on until the furnace is almost full, finishing off with a coating of ashes over the top and front of the glowing mass. Then push the chimney damper almost home, leaving only a space of about an inch for the passage of the smoke. If this is carefully done, it is probable that in the morning it will only be necessary to clear out the clinkers, increase the draught, and add a little more fuel, to start the fire for the day. If not, it will show that too much draught has been allowed, and much fuel used in proportion to the ashes, which can be remedied the following night. It will be necessary in the morning to clear out the clinkers very thoroughly, and also to remove the ashes from the sides of the boiler by using the clinker bar energetically between the bottom of the boiler and the side pipes and flues of the furnace. This operation should be repeated once in the afternoon, and again in the evening, allowing the fire to burn somewhat low in order to make it easier. The flues should be thoroughly cleaned out three times a week during the winter and early spring, beginning with the top central flue, cleaning the pipes or dome (in the case of a saddle-boiler) with a small hoe and brush worked well in among the top and side pipes. Afterwards draw the ashes and soot out of the bottom flues on either side of the base of the furnace, and clear the base of the boiler in the furnace. The tools necessary for the proper stoking and cleaning of the furnace consist of a shovel hoe, about 7 inches wide

and 5 inches deep, with a long, stout iron handle, for pushing the fire back in the furnace, and drawing the ashes from underneath; a hoe about 2 inches wide and 1 inch deep, attached to a light iron handle, for cleaning the flues; and a poker and clinker-bar combined, which must be strongly made, to stand the strain of removing and breaking the clinkers in the furnace.

With regard to fuel, there is no doubt that anthracite coal is the best; but as the heat is generated quicker with coke, the best plan is to start the fire with coke in the morning, and afterwards use the anthracite. If the fire is made up at ten p.m., there will be a clear fire eight or nine hours later, and the houses will be well heated. Anthracite is very hard coal; ordinary coal burns away much more quickly, and is therefore not only less economical, but requires more frequent stoking.

Stoking is an art which can be acquired by anyone of ordinary intelligence, and the satisfactory working of the boiler depends to a very great extent on how it is performed. The greater number of boiler troubles may be prevented by good and careful stoking. *M. E.*

ORCHID NOTES AND GLEANINGS.

LAELIO CATTLEYA HONORIA.

A NEW cross between *Cattleya Mantinii* (Bowringiana × *Dowiana aurea*) and *Laelio Cattleya* (Geo. Woodhams (C. Hardyana × *L. purpurata*)) is sent us by Messrs. Armstrong and Brown. With four species of *Cattleya* in its composition to one of *Laelia*, it naturally takes the large-flowered *Cattleya* shape and character to a great degree. The flower, which is 6 inches across, has silver-white sepals tinged and slightly veined with mauve, and broad, rosy-mauve petals, waxy at the margin. The lip, which resembles that of *C. Mantinii*, but is broader and more openly displayed, is rose colour at the base, ruby-red in the middle area, and light violet in front. The centre has a fine veining of bright yellow.

CYPRIPEDIUM MURIEL VAR. AMETHYST.

A MASSIVE flower of this fine cross between *C. Hera Euryades* (Boxallii × *Leeanum*), and *C. Cynthia* (mitsis-Leeanum × *Charlesworthii*) is sent us by R. Windsor Rickards, Esq., Usk Priory, Monmouthshire. The flower is of very thick substance, the dorsal sepal amethyst purple with an olive green tint at the base and clear white margin and apex. The broad petals are honey-yellow lined and veined with mahogany-red. The lower sepals, which are together nearly as broad as the upper sepal, have the central half coloured emerald green the two sides, extended wing-like, white with amethyst-purple markings, as on the upper sepal. Such an arrangement is considered abnormal, but the character is known to be fixed in some varieties. It would be interesting to know whether it proves so in this case. The name Muriel has also been given to the cross between *C. Chamberlainium* and *C. tonsum*, both raised in Sir Geo. Holford's gardens. The R.H.S. list recognises the cross now noted.

CATTLEYA TARENTINO ALBA

A FLOWER of a cross between *Cattleya Warneri* alba and *C. Dusseldorf* alba is sent by J. Ansaldo, Esq., Rosebank, Mumfles, Glamorganshire. It is a very good addition to a class of crosses of the *C. labiata* section, and which, while bearing a resemblance

to each other, are all good, and have the merit of flowering at different seasons, determined by the flowering time of the parent used. *C. Warneri* always has a good effect on size and form in its descendants, and the present flower follows the albino form of that species closely, the *C. Dusseldorfæ* alba (Undine), which resulted from crossing *C. intermedia* alba and *C. Mossiae*, Wagner) appearing chiefly in the narrower and more crimped front of the labellum. The flower is white with a slight sulphur yellow tinge in the tip, the disc of which is bright orange colour.

THE ROSARY.

ROSE AMERICAN PILLAR AND ITS ORIGIN.

The interesting account of the origin of this Rose as given by the raiser on p. 132 will appeal to all Rosarians, and especially those engaged in the raising of new Rambler and climbing varie-

Léon Simon and *Pierre Cochet*, issued so far back as 1899, but supplemented with the parentage so far as known of the varieties catalogued. This work contains some 10,394 names. To compile such a catalogue would be a great task, but the National Rose Society might well collaborate with, say, the American Rose Society for the carrying out of the work.

America is in advance of this country in the matter of trial gardens, and I have before me an application from the Mayor of Portland, Oregon, to send novelties of my raising to their new National Test Garden, to be conducted under the direction of the Bureau of Parks of that city.

Catalogues giving the parentage of Roses are of valuable assistance to the Rose breeder. From one before me of Peter Lambert's, I find that the parentage of that very fine climber *Marie Henriette Gräfin* (Hotell) is given as Rambler *The Farquhar* × *Richmond*. This is a very fine climber, and reminds me much of Paul's Scarlet Climber in growth, although it is quite distinct in blossom. The flowers are a delightful scarlet-

NOTICES OF BOOKS.

THE GRASSES OF THE WEST INDIES.*

A COMPENDIUM of the grasses of the West Indies is a welcome addition to botanical literature, and if the work before us does not satisfy all requirements it goes a long way towards doing so. It is the joint work of the agrostologists of Washington and the result of upwards of 25 years' investigations and study, aided by numerous American botanists and the British botanists on the spot. The compilation is based primarily upon the study of collections in the United States National Herbarium, and it comprises 455 species belonging to 110 genera, including a number of naturalised kinds. Prominent among the British contributors are Messrs. W. Harris, W. G. Freeman, J. Hart and W. E. Broadway, and the Trinidad Herbarium. The total number of specimens dealt with is nearly 7,000, and these are de-

FIG. 75.—THE LATE MR. WILLIAM MARSHALL, V.M.H., IN HIS GARDEN AT "AUCHINRAITH," BEXLEY.
(The plant in flower is Rose *Crimson Rambler*.)

ties. Hybridisers have long been aware of the great possibilities accruing from a mingling of the different species and by intercrossing several times with various objects in view. Gruss an Teplitz resulted from a blending of several varieties, and that king of sturdy Roses, *Conrad F. Meyer*, was produced from a hybrid (*Gloire de Dijon* × *Duc de Rohan*) × with *Rosa rugosa germanica*. Messrs. A. Dickson and Sons adopt these methods with well known results, and Mr. M. Grady showed me one seedling, itself a cross with *La France* that had already produced for him several Gold Medal Roses.

It seems to me that the work of producing new types of Roses would be vastly assisted were there some authoritative work giving the origin of all known Roses, or so far as such knowledge is available—a catalogue of all introductions to date on the lines of that gigantic work of Messrs.

red and of good size and form. I can strongly recommend it. But we want Ramblers that will give us good autumnal displays, and to this end I suggest we choose parents from the perpetual-flowering kinds. Why not utilise such fine climbers as *Climbing Cramoisi Supérieure* as seed parents? This splendid climber is flowering with me now (November 5) quite profusely, and it gives a very brilliant touch of colour to the Rose garden. From the useful work of Messrs. Simon and Cochet already referred to, I find it is synonymous with *James Sprague*. May I be permitted to express the hope that our botanical societies, both at home and abroad, will continue to give us some good crosses with various species, so that the Rose breeder may have good material to work upon, in order to evolve other fine Roses of the American Pillar type? *Walter Easton, Farnwood, Leigh-on-Sea.*

published in the U.S. National Herbarium. "To facilitate the use of the work as a manual the detailed citation of specimens under each species is omitted. Appended to the paper, however, is a list of all the numbered specimens of West Indian grasses in the U.S. Herbarium." This list runs to 66 pages, and it will be of great service to other establishments possessing sets of the same series, such as those of C. Wright, Sintenis, Eggers, and others. The whole of the text is in English, and the descriptive part is a system of keys to the tribes, genera and species, followed by brief descriptions. All useful synonyms are cited, as well as generally accepted English names, and current vernacular

* *Contributions from the United States National Herbarium*. Vol. XVIII., Part 7. Pp. 261-471 + xviii. "Grasses of the West Indies." By A. S. Hitchcock and Agnes Chase. Washington: Government Printing Office, 1915.

names are also given. A full index of some 1,500 names and synonyms completes this work. *Panicum* and *Paspalum* number about sixty species each. The *Bambuseae* (*Bambosaeae* of the authors) are represented by four genera and sixteen species, twelve of which belong to the climbing genus *Arthrostylidium*.

ON INCREASED FOOD PRODUCTION.

WINTER PARSLEY.

To obtain a good supply of Parsley in winter plants should be lifted and planted in cold frames, skeleton pits, or at the foot of south walls. Choose the latest sown plants for this purpose and they will produce leaves all through the winter and spring. Where small plants are not available older specimens should be lifted and treated in the same way, cutting off the larger leaves. At the time of planting thoroughly water the roots, and give the soil a good dressing of soot. Seed may also be sown thinly in boxes, germinated in gentle warmth, and the seedlings grown on in cool houses.

EARLY PEAS AND BROAD BEANS.

EVERY effort should be made to produce pods of Peas and Beans as early as possible during the coming year. It is the common practice of many to sow early varieties on warm borders in the open during the autumn. In many parts of the country this often proves to be a very precarious method, due to the weather and various kinds of vermin. A much safer and more reliable plan is to sow the seed thinly in well-drained boxes about 4½ inches in depth, and germinate them either in cold frames or cool houses, planting the seedlings on well-prepared land, in the spring. Both early Peas and Broad Beans do much better when treated in this way than sowing out-of-doors. The seeds germinate better, the young plants are easily kept under control, and when carefully planted they suffer little or no check, and give far better returns than when sown in the open.

Good varieties for present sowing are, Peas: Early Giant, Edwin Beckett, Early Morn, and Duke of Albany. These sorts are much to be preferred to round-seeded varieties, as they give heavier crops of far better quality, and are only a few days later. Of Broad Beans, Aquaduke and Leviathan are two good and reliable sorts. *E. Beckett*.

ITEMS IN STORE FOR WINTER.

BESIDES the more ordinary store vegetables, such as Beets, Carrots, Swedes, Turnips, Choux, cabbages, Sugar Parsley, Parsnips, and bottled fruits, such as Plums and Pears, it may be of interest to note other items.

Pumpkins.—Some of these failed to mature, and the juicy stalk was certain to mildew, so the stumps have been rubbed with sulphur and soaked with "lime sulphur," previous attempts at sealing with resin, etc., not having been a success.

Crosses have been a failure; they are best started by putting one to three corms in small pots sunk in the ground and planting out when well started. Owing to my absence from home last spring, this was not done.

Chinese Yam only amounts to a few pounds, as last year's remaining tubers were mostly given over to new tubercle production for next season. I may note that those left in the open ground stood the severity of the winter (three successive nights about 0° Fahr.), whilst those in a cold greenhouse bed were destroyed.

Beans.—A ten-yard row of four varieties of Runner Beans has yielded just over 4 lbs. of ripe seeds after supplying green Beans and a dish or two of flageolet; Dwarf Beans for dried ripe Beans have not yet been threshed out. The plants were sown in Rose beds, vacant places on the rockery, and other available nooks; a few remain, too, from last year. Some have been bottled in the flageolet state, as amongst other ends they

are better for succotash; moreover, one can use pods thus which are too immature to ripen and too old for "baricots verts." Young pods have also been dried after four minutes' scald in boiling water. *Broad Beans* picked young and shelled have been dried direct; preliminary scalding seems to be a mistake.

Sweet Corn (Maize) has been boiled, scraped off, and bottled for succotash.

Tomatos in two forms, juice bottled in small bottles so that a whole lot can be consumed at once on opening, and as *Massa Quince* have been similarly treated in "Massa" form, and in prospect some *Medlars* will be treated likewise, on recommendation of the old description that the Quince is used, "like the Medlar," for

French seem to be late varieties. Victorias were a huge crop, but none was dried, as they were not likely to yield a good product. After all, they are only fit for the market or the pig-pod.

Grapes from the cool greenhouse. Many bunches of Grapes have already been dried off. Last year we made our first cake with our own raisins. The outdoor ones are now going through.

All the drying has been effected either in the hot "linen airing" cupboard or in a recess which has been closed in about the independent stove which heats the cupboard. Plums take about a week, ten days, or more, and should be occasionally inspected and turned. One day is about enough for Beans, and Grapes may be left forgotten till Christmas if hung somewhere out of

FIG. 76. ROSE AMERICAN PILLAR.

(See p. 190.)

flavouring Apple tarts; as there is no need for bottles or for immediate use of sugar, this form of storage seems useful.

Plums. Besides those in jam or bottles, Plums have been dried, the main lot being Reine Claude Violette, which we found before the war made a very superior prune; also experimentally, for their qualities have not yet been tried, we have Early and Late Orleans, Pershore, Belle de Louvain (these two need care, as they are thin skinned), Autumn Compté (smells good), Jefferson and Monarch (these two seem very promising); also a late Plum said to be the old Mussel or muscle Plum (still good and fresh), is now being dried. This, too, looks full of promise. I may note that the Plums dried by the

the way. As the heat is never high, the ripening process continues and a more sugary product seems to result. We fancy, too, that incidentally better flavour is obtained than in the quickly dried bought Prunes. In fact, some of the Plums we had stewed were put for a couple of days in warmth to make them more sugary. Moulds will not grow so long as the temperature is even so little raised as body temperature. This mode of drying is probably much too slow for elsewhere than the household. It is made slower in practice by the intermittence of the heating; anyhow, a day's cooling does no harm, and we began its use before the war. In some drying on the market the fumes of combustion pass directly on the fruit, which is hardly to be desired. *H. E. D.*

POTATO WINDSOR CASTLE.

I know of no better Potato for cropping qualities and exhibition than Windsor Castle. Can any reader name one? To-day we are thinking about the crops for next season, and the changing of seed Potatoes to produce as many tubers as possible. In planting, many of us are guided by the seedsman's list as to the season for which different varieties are best suited. Some list Windsor Castle as a main crop; another, mid-season; and there is a big difference between main crop and mid-season. Many gardeners at the present time are helping garden and allotment societies to produce as much food from the ground as possible; and many members of these societies require a fair amount of Potatoes every day, where the families are large. Gardeners are often asked to recommend a Potato for quality, liberal cropping, and earliness. Would any recommend Windsor Castle? The seedsman says in his catalogue, for mid-season or main crop. I should have no hesitation in naming Windsor Castle. When planted as a main crop, it is liable to bad attacks of disease, but by planting early and lifting early very little disease is seen. *C. Davis, Holy Wells Park Gardens, Ipswich.*

EARLY AND SECOND EARLY POTATOS.

In response to Mr. Wm. Taylor (p. 191), I may say there is no lack of varieties of Potatoes to give the qualities he desires, if they are given favourable conditions. All of them crop heavily, and in such cases we must expect a correspondingly strong haulm, and occasionally longer or taller than he mentions. In gardens of no great width and surrounded by walls or close fences they often grow twice as tall as they ought, but in open gardens, allotment ground, and in fields they abide by their respective heights unless over-matured. May Queen, Ninetyfold, and Dumottar Castle are white kidney and pebble-shaped Potatoes, of mealy character and excellent flavour, ready for use during the first and second weeks of July. Duke of York, Midlothian Early, and Witch Hill follow them towards the end of July, judging by my experience of them this year, but it all depends on soil, situation and season. One large grower, at least, is accumulating seed of Witch Hill from private sources, because it is new, and he has discovered it to be excellent and a heavy cropper. Of the same type as Eclipse, mentioned by Mr. Taylor, I can add Early Puritan, Epicure, and British Queen, which are descendants from such American types as Beauty of Hebron and Early Rose, and betray their origin by their shape and by being often flushed with pink. White Beauty of Hebron originated in this country from the ordinary pink-skinned type. White Elephant is of the same type, but larger. This and the Hebrons are old varieties, but still much grown for market. They come into the greengrocers' shops in our district before the skin is fixed. I should call them second earlies, or British Queen, mid-season. Great Scot is also a mid-season Potato, fairly mealy, but more so when baked. The last two will keep till spring, and that applies to Witch Hill and others of its group, when stored in favourable conditions. *J. P.*

FOOD VALUES

An article in the *Scientific American*, July 29, by Dr. C. F. Boldman, advocates the affixing of food values (in calories) to all articles of food. At his suggestion a firm of New York restaurateurs has adopted the practice, and on its menu cards may be read: 632.429, cold ham or corned beef—which means that if you choose the former dish you have one providing 632 calories; if the latter, you only get 429.

This appears to us to be a very sound method of teaching food economy, and one the principle of which might be adopted in this country. How many people, for example, among the general public know such an at present all-important fact that the protein of Potatoes is, weight for weight, four times as valuable as human food as is the protein of Wheat?

The Week's Work.

THE KITCHEN GARDEN.

By J. DUNN, Foreman, Royal Gardens, Windsor

SEAKALE.—The foliage of Seakale having been killed by frost, a batch of roots may be lifted and placed in heat. Only a few roots should be lifted for this first forcing, as better results may be expected later from crowns that remain in the ground for another week or two. If only a small supply is required the roots may be placed in pots or boxes closely together and the space between them filled with fine, sifted soil, which should be pressed tightly with the fingers. If the soil is dry water it thoroughly. Place the pots and boxes containing the roots in a perfectly dark pit or shed where the temperature is 60°, and keep the atmosphere moist. Large numbers of roots may be forced quite easily on beds of fermenting material, which may be made in any brick pit where fire-heat is available when necessary. The bed may consist of fallen leaves, which should be made quite firm by treading; place a layer of old potting soil on the surface to a depth of 9 inches. The roots may be planted with a spade in the same manner as Box is planted for edgings. The crowns should be placed closely together in the rows, which should be 6 inches apart. Forced Seakale will keep in good condition for 6 or 8 days after it is cut. At Frogmore we force about 20,000 crowns in batches of about 1,500 each. Water should be applied as the roots are placed in position, and the soil made firm.

WINTER SALADS.—Pits in which Lettuce and Endive are growing should be freely ventilated whenever the weather is favourable. Hoe the surface of the bed carefully, and do all that is possible to promote a healthy atmosphere. Lettuce plants which are advanced in growth are liable to damp off during the winter in dull, damp weather. Lettuces may still be planted in pits from the seed bed, with a view to producing a supply early in spring. Endive should be blanched as required by placing a few sheets of brown paper over the plants. Plants of Batavian Endive should be lifted from the open border and placed in pits at once or they may be injured by frost.

CHICORY.—Roots of Chicory should be lifted and placed in a warm, dry pit or forcing house where light can be excluded. This is a valuable salad plant, and very easily forced. The roots may be placed in pots or boxes in the same manner as Seakale.

WINTER SPINACH.—When the ground is sufficiently dry work the Dutch hoe carefully between the rows of winter Spinach. Remove all weeds and decaying leaves, and if slugs are troublesome dust the soil with soot.

BROAD BEANS.—To obtain early pods of Broad Beans make a sowing as soon as the ground is dry enough. Select a sheltered position where the soil is light and rich. Sow the seeds in shallow drills, using double the quantity usually sown in spring to provide against loss. Broad Windsor and Beck's Green Gem are suitable varieties.

BETROOT.—All Beets should be lifted and stored in a ramped shed. The roots should be stacked in sand or fine, dry soil to prevent shrivelling. It is very important to keep them beyond the reach of frost.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to the Hon. ARTHUR J. DAVEY, Abbots Wood, Godalming, Surrey

RASPBERRIES.—The Raspberry requires a rich, well-drained soil and an open situation. The plants are sometimes grown in odd corners, but with unsatisfactory results. The best varieties are: Hornet, Norwich Wonder, Superlative, Baumforth's Seedling, Yellow Antwerp, and, for autumn fruiting, Belle de Fontenay. Yellow sorts are not so largely grown as their merits deserve. They make a very useful and pretty

dish for dessert. If the soil has been recently trenched it will not be necessary to trench it again, but if hard and infertile it must be well tilled and plenty of burnt soil, lime rubble, or anything else that will lighten it mixed with it. Well decayed farmyard manure should also be employed. The best system for training, and the least troublesome, is to secure the canes to horizontal wires stretched from iron standards. If wooden posts are used they should be cross-tied to increase their durability. The posts should be a foot above the wire to permit of placing the nets in position in the fruiting season. Three wires will be sufficient, the first about 2 feet and the top one 6 feet from the ground level. The canes should be planted about 1 foot apart. Place a mulching of dry litter or bracken Fern over the roots to furnish protection from frost. It is not advisable to plant in wet weather, and especially on heavy ground. In established plantations the canes may be tied to the wires in their full length at the first opportunity. In the spring the ground and air are often very cold, and such work is then slow and tedious. Do not tie the canes closely together, and remove all weak shoots if this has not been done already. A liberal dusting of either soot or lime may be given after the soil is cleared of all rubbish. A mulch, if manure for the purpose can be obtained, will be an advantage.

RED CURRANTS.—The bushes may be pruned at any time after the fall of the leaf. If the branches have been summer pruned the main shoots will not require much shortening, but if the bush is as large as is desirable, hard pruning will then produce the best results. Spray the plants with paraffin emulsion to prevent birds eating the buds; another good plan is to slack some lime with paraffin and to dust the bushes with the material when they are damp.

BLACK CURRANTS.—Examine the bushes for "big bud" (if this pest is seriously in evidence the bushes should be grubbed up and burnt), and then prune them. The Black Currant does not require much pruning beyond thinning out the wood and making the plants shapely. Very old bushes should be discarded and young stock planted in a different site if the soil is exhausted. Black Naples and Boskoop Giant are good and prolific varieties. A good spraying with winter wash may be afforded the bushes, especially those growing in damp soil, where the wood becomes covered with moss and other foreign growth.

GENERAL REMARKS.—Push forward the work of planting, root pruning, stake making, tying, and pruning. Have the ground ready for planting the trees by the time they arrive from the nursery.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gaton Park, Reigate.

VANDA.—Tall-growing Vandas of the tricolor and savais sections are commencing to root freely, and will continue to do so all through the winter. The present is a suitable time to re-pot or resurface the plants; if this work is deferred until the spring, there will be a greater danger of the bottom leaves dropping. It is not advisable to disturb specimens that are well furnished with leaves if the present pot is sufficiently large to accommodate the roots for another season, but such plants should be provided with fresh material on the surface, removing a quantity of the old surface compost. Plants that have lost many of their leaves at the base and are furnished with live roots some distance up the stem, should have the old potting and drainage materials taken away, without detaching the roots which are clinging to the sides of the pot. After cutting the base of the old stem away, place a flat piece of potted over the drainage hole, stand the plant in the centre of the pot sufficiently low down, if possible, to bring the bottom leaves near to the rim, arrange the roots in position, taking care not to break them, and fill in around and between with clean crocks and rough Sphagnum-moss, pressing the materials firmly and arranging them nearly to the top of the pot, finishing with a deep layer of clean, jacked Sphagnum-moss. Secure each shoot to a neat, strong stick. Well rooted specimens,

with plenty of lower leaves, that are growing in pots too small for another season, should be re-potted. These newly potted plants should be sheltered from direct sunshine, and their immediate surroundings kept moist by frequent syringings around and between them. It is essential that the plants be always stood on a damp bottom. Direct watering will not be necessary for a few days after potting, but as often as the moss on the surface of the pots becomes dry it should be sprinkled with clear water to keep it alive. When new roots begin to push out from the stem and from the points of the old roots, the amount of water should be gradually increased, but the moss should never be kept in a saturated condition. The plants delight in plenty of fresh air, and the bottom ventilators near them should be opened at all times when the external temperature is not lower than 50°. These *Vandas* grow best in the intermediate house, or at the cooler end of the Cattleya house. The leaves and stems of the plants should be sponged with a suitable insecticide to cleanse them from dust and insect pests. A small brown scale insect attaches itself firmly to the leaves, and great care should be exercised in dislodging the pest, or the leaves may be damaged. *Vanda Kimballiana* and *V. Watsonii* are developing their flower-spikes—the atmosphere of the house in which they are grown should be kept rather warmer and drier than hitherto, but sufficient water should be afforded the roots at present to keep the Sphagnum-moss growing.

COELOGYNE.—Plants of *Coelogyne cristata* and its varieties are nearing the completion of their season's growth, and will soon be developing the flower-spikes from the new pseudo-bulbs. When this stage is reached reduce the amount of water at the roots, but not to such an extent as to cause the plant to suffer. For the present give just sufficient moisture to keep the pseudo-bulbs rigid. Well-rooted, pot-bound specimens will be greatly benefited from now onwards to the flowering stage by occasional applications of weak manure-water prepared from cow-dung, *C. lagartii*, *C. mollis*, and *C. olata* are also developing flower-spikes, and should be well supplied with moisture.

MASDEVALLIA. Plants of *Masdevallia tovarensis* are commencing to develop flower-spikes, and specimens that have been grown in cool conditions during the summer should be placed in a light position in a house having an intermediate temperature. Exercise great care in watering these plants. The compost should become dry before water is added. When watering the house remove these plants to another division or the flowers will be changed from white to pale pink.

THE FLOWER GARDEN.

By W. J. GRISE, Gardener to Mrs. DEMSTER, Keele Hall, Staffordshire.

TREES AND SHRUBS WITH ORNAMENTAL FRUITS. During the present planting season the merits of trees and shrubs bearing ornamental fruits should be considered, for a good specimen of a *Platanus Platanus* with its bright scarlet fruit, always attracts attention. Most kinds are best planted in groups, but each individual specimen should be given sufficient space for its full development. Amongst the finest of leaved trees and shrubs are *Cotoneaster frigidula*, *C. Simonsii*, *C. nonnifolius*, *Symphoricarpos racemosus*, *S. vulgaris*, *Berberis Darwinii*, *B. Gayi*, *Crataegus pendula*, *C. Carmoi*, *C. Pycnantha*, *Lalandii*, *Eugonius europaeus*, *Perrotteta*, *Skimmia japonica*, *S. fragrans*, *Parus Anoparia* (Mountain Ash), *P. M. his var.* John Downie, *P. arbutifolia*, *Viburnum lantana*, and *Elaeagnus macrophylla*. They should be planted in groups to secure the best effect. Some of those enumerated do equally well when planted under large trees, and for this purpose the list may be extended by the addition of *Hollies* in variety, *Veronica Traversii*, *V. buxifolia*, *Weigela*, *Bibes*, *Portugal Laurels*, *Lacustrum japonicum*, *Rhododendron ponticum*, and *Berberis Aquifolium*. The ground should be trenched and manured, for usually the soil under trees is in a more or less exhausted condition, and unless it be thoroughly prepared before planting success cannot be expected.

PLANTING RHODODENDRONS. If the ground has been prepared in advance, the planting of *Rhododendrons*, *Azaleas*, *Andromedas*, and other American shrubs should be preceded with care, as autumn planting is always the most satisfactory. In some districts it may be necessary to mix peat and sand with the soil, according to its character, reserving a quantity of these materials to place about the roots when the work of planting is done. Do not place the roots too deeply in the soil, but set them at the same depth as they were before the plant was lifted. Firm planting is essential in the case of all members of the Ericaceae. Do not plant when the soil is wet or frozen. Secure to stakes at once those that require a support, as nothing is more injurious to the roots than twisting and loosening by the wind. A mulch of leaf-mould or stable litter will protect the roots from frost, and promote root action.

SPANISH LIRISES.—The planting of bulbous *Lirises* should be done forthwith as they are very difficult to keep alive when out of the ground. Plant in groups in well-sheltered beds or borders in rich, sandy soil. A good selection of Spanish *Lirises* is afforded by the following varieties:—*Blanche Superbe*, *Vondel*, *Earl of Leicester*, *Mulvey*, *Chrysolera*, *Humboldt*, *Mon. Byron*, *Cajmans*, *Solferado*, *Admiration*, *Belle Chinoise*, and *Thunderbolt*. Plant the bulbs 4 inches apart and 3 to 4 inches deep. English *Lirises* form a subsection to the Spanish section, and require similar treatment, but it is advisable to allow a little more space between the individual bulbs. A fine effect can be obtained by planting a selection of the best varieties in groups in the foreground of herbaceous or mixed borders.

FRUITS UNDER GLASS.

By JAS. HUTTON, Head Gardener at Gunnersbury House, Acton, W.

PINEAPPLES.—Stickers that were potted during the past season should now be well rooted in moderately small pots. Six-inch pots will be large enough for plants of moderate size, and will suffice through the winter. Do not allow these young plants to become excessively dry at the roots, and in watering use water a few degrees warmer than the temperature of the house, say 70°. The temperature at dusk should range from 60° to 65°, and at daybreak 55°. Higher temperatures would cause too much growth in winter. For instance, if the temperature is too high and the plants dry at the roots, some of the stock may develop fruits prematurely. Plants that are in their fruiting pots, say, from 12 inches to 14 inches diameter, may be kept moderately dry at the roots for the next three months. Then, when the days are again lengthening, and water is given a little more liberally, the plants will respond readily. The atmospheric conditions should be on the dry side also; damping down is permissible, but do not use the syringe more than for light spraying between the pots. It will result in a saving of fringing to cover the glass with suitable material at night during frosty weather, and for this there is nothing to equal brown tanned sheeting.

CLEANING FRUIT HOUSES.—Let the fruit houses and trees have a thorough cleaning. It is advisable to get this work done in good time, in order that the work of resting Peaches, Nectarines, and other trained trees may be proceeded with as soon as possible. A weak solution of soft soap and paraffin is a good mixture for cleansing purposes. Use the water fairly warm for the scrubbing of the woodwork, syringing some of it vigorously into every nook and cranny. Wash the glass both inside and out. Let the walls also be well cleaned, and afterwards whitewashed, using quicklime mixed with a little salt to assist in setting the lime. If the houses are at all leaky endeavour to have them painted; there is no better time than the present for doing this work.

RESTING THE FORCING HOUSES.—Early in the year I referred to the need for deferring the very early forcing of fruit trees, including Vines, during the war, and recently I was in a neighbouring garden where this had been practised. It was a house of Muscat of Alexandria Grapes, the crop of which in pre-war days was ready for cutting by the end of May.

In ordinary circumstances these Vines would have been exhausted in a few years. Now, by a few years' normal treatment, they are again in the very best condition, and carrying at the present time a well finished crop of large bunches. I noted, too, that the wood is well ripened for another year, and the Vines bid fair to continue yielding good crops in the future. The borders are inside, hence they are under full control. If needed the Vines will be suitable to hard forcing in subsequent years, and in all probability, when the war is over, such forcing will be resumed. The house is of moderate dimensions and well adapted for forcing. I am convinced that it will pay to allow the plants a rest from hard forcing for a few years, and more especially at the present time, when there is not an urgent need for early forced fruit. Besides Vines my remarks apply to Peaches, Nectarines, other stone fruits, and Figs. It affords an opportunity of getting the trees into a better condition. In the case of both Peaches and Nectarines it affords an opportunity of thoroughly re-making the border, also of carefully thinning out the growths previous to training in healthy, fruit-bearing wood. Even in the case of fruit trees in pots, resting them from hard forcing for a few years will give new life to the trees, and it will be an additional advantage if lighter crops are taken from them meanwhile. Trees that have been previously forced early will start into growth naturally earlier than those that have not. By avoiding forcing unduly early a very considerable economy of fuel will result, and this is all-important from a national point of view. At Gunnersbury House Gardens the boilers and pipes are being emptied in two different stockholds, and I am arranging to dispense with the houses which they heat during the winter. This will meet both the Labour shortage and the fuel consumption.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to Lady NORRICH, Eastwell Park, Kent.

CLERODENDRON FALLAX.—This handsome stove shrub is very distinct from the climbing species of *Clerodendron*. The vivid scarlet flower-heads are very showy, and well-grown plants are useful for decorative purposes at this season. As the plants approach their best, the amount of atmospheric moisture should be reduced, and a little more ventilation given. The pots are filled with roots, and the soil must not be allowed to become dry, or the foliage will quickly lose its freshness. At this stage feeding should be discontinued. When the plants are past their best, and becoming shabby, cut off the flower-heads back to the stem, and gradually reduce the water supply to the minimum during the depth of winter, thus ensuring the plants a good rest before starting them into growth in the spring. These old plants may thus be flowered much earlier than seedlings.

PLUMBAGO ROSEA SUPERBA.—This attractive winter-flowering plant will soon be coming into bloom. In order to develop the delicate colour of the flowers, arrange the pots thinly apart, and as near to the roof-glass as possible. When the spikes commence to open, remove the plants to a somewhat drier atmosphere than the ordinary plant stove in which they have been growing, as in drier, cooler conditions the flowers last longer. If required, the flowering season of these plants may be prolonged by keeping a batch in a cooler house, but the temperature should not be allowed to fall below 55°. When the flowers are over, if the spikes are cut out, the plants given a pinch of artificial manure, and returned to the stove, they will develop a second crop of blooms.

LATE-FLOWERING TULIPS.—As soon as May-flowering and Darwin Tulips are received from the salesmen those intended for pot culture should be potted without delay. They will succeed in pots, pans, or bowls of almost any size, but for general greenhouse purposes 5 and 6-inch pots are the best receptacles. If large specimens are required, 12 to 18 bulbs (according to the variety) should be placed in an 8-inch pot. As soon as the pots are well filled with roots they can be assisted to develop by a little warmth. But they must not be hard forced; encourage them to grow by sun heat as much as possible, and place them close to the roof-glass.

EDITORIAL NOTICE.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER, and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and such unnecessary delay and confusion arising from letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 42.2.

ACTUAL TEMPERATURE:—Gardens' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, November 15, 10 a.m., Bar, 30.0, temp., 41. Weather—Fair.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—Bulbs at 67 and 68, Cheapside, at 3 o'clock, by Frotheroe & Morris.

Gardening in India.

Gardening has become —for better or for worse —one of the most cosmopolitan of arts, and the influence of the modern British schools of gardening is making itself felt in all parts of the world. Whether it is better for a country like India to develop gardening along independent lines rather than to follow precedents developed in relation to British gardens is a nice question, but of this we may be sure, that so long as India is the temporary home of men and women of British origin, so long will the attempt be made to plant English gardens in India.

Though the plants which adorn these British-Indian gardens will perforce be different from those we grow here, the British-Indian gardener will insist on lawns and borders and gravel paths. His lawns must be of Doob-grass or Hariali (*Cynodon dactylon*), made by transplanting turves or dibbling or spreading mud with chopped plants, and renewed triennially. Even so, the Indian gardener will have to weed as arduously as his British confrère. In making his lawn he will be well advised also to practically sterilise his soil, just as we do, or should do; for otherwise his battle with weeds will be as arduous, and well-nigh as hopeless, as is ours nowadays.

The Indian flower-borders may, however, contain not a few representatives of those genera which contribute to the beauty of

British gardens—Dahlias and Cosmos, Tithonias and Zinnias, Coreopsis and Tagetes and Gerbera. Nor, at all events in many districts, will Roses be absent. For the British-Indian garden must always be a reminiscence of home, as well as a source of pleasure in itself, and he must indeed be a cosmopolitan who would not include in his garden many of the flowers the scent and sight of which evoke memories of the gardens of home and of childhood.

Messrs. Burns and Little have, consciously or unconsciously, borne these ideas in mind in writing of ornamental gardening in India.* How difficult it is to generalise on a subject of such magnitude may be judged from the fact that the garden of India must be prepared to flourish under a rainfall which may be nil or may reach 300 inches per annum. Irrigation must therefore play a large part in Indian gardens, and we think that the authors might well have given more space both to methods of irrigation and to the use of water in garden design. Water and shade—moving water and deep shade, as of the Boboli Gardens at Florence—would seem to us to be essential conditions for Indian gardens in hot places where water is to be obtained.

The need for forethought and prompt action essential to successful gardening everywhere, is even more vitally necessary in Indian gardening than it is at home. If the Indian gardener misses the tide in the affairs of the garden, his year is lost, for where air and soil are hot and humid the order of the garden, unless maintained by a ready hand, is turned to anarchy.

The authors are not too vocal in the praise of the native mahi—the Indian gardener. He appears to be ever clamant for more assistance, and the area which one mahi can look after is only about one-tenth of an acre—not much more than an allotment; but climate counts both in limiting the time during the day when hard work may be done and in limiting the willingness and fitness to do hard work—and gardening is, and must always be, hard work.

It may be presumptuous to offer an opinion, and not to trust implicitly the man on the spot, but we cannot agree with the authors in advocating the British system of flower-beds cut out of grass—of more or less formal shape. As the authors observe, "to some these appear inartistic." Nor can we agree that a flowering border should be so disposed that the tall plants are always at the back and the dwarf at the front:—

"Trim little scholars are the flowers of my garden,

Taught to stand in rows and answer to their names."

We gather that the rock garden has yet new worlds to conquer, for on this subject the authors are silent. Nor do we suggest that any but the extreme would advocate a rock garden in the plains of India; yet in that vast territory there must surely be many places in which the rock garden would be at home.

THE BOTANY OF BURNHAM BEECHES.—Mr. J. G. BAKER has published a list of the species of plants occurring in the 374 acres of forest land which constitute Burnham Beeches. About half the area is woodland and half common. The soil consists of sand and gravel, and the flora is not a large one. Mr. BAKER estimates that the plants—Beech, Birch, Holly, Bracken, Ling, Bell Heather, and the grasses *Deschampsia flexuosa* and *Molinia caerulea*—occupy three-quarters of the whole area.

HORTICULTURE AND THE BENCH.—New Justices of the Peace for the City of Glasgow include the names of Mr. A. N. HUNTER, proprietor of Messrs. ACSTON and McCASLAN'S seed business, and Mr. JAMES WHITTON, V.M.H., chief officer of the City Parks and Open Spaces.

GERMAN PRISONERS ON THE LAND.—The Food Production Department states that more and more German prisoners are being employed on the land, the popular impression that very few indeed are working for their living being incorrect. In different parts of the country, camps of German prisoners have for some time past been engaged on drainage and other important work. In Worcestershire alone during the week ending October 27, German prisoners engaged in agriculture worked 21,762 hours, as compared with 19,694 hours in the previous week. Some water-course cleaning in Cheshire by German prisoners has been most favourably reported upon; in Essex they are lifting and storing Mangolds.

WAR ITEM.—Eight large Pears, sent by Mr. CECEL BALDWIN, Jersey, to Messrs. ALLAN, The Bazaar, Glasgow, to be sold in aid of the funds of the Glasgow Red Cross Fund, realised the sum of £26 10s.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE LATE MR. WORTHINGTON G SMITH.

The portrait and notice of the late Mr. W. G. Smith, on p. 169, recalls memories of days past, when wood engraving was the principal, if not the sole means of illustration, and when the names of such artists as Birkett Foster stood high in the world of illustration. There was a great demand for good box-wood, and Mr. Worthington Smith was one of the first artists to interest himself in the discovery of a substitute. At an International Forestry Exhibition which was held at Edinburgh in 1884, a silver medal was offered for a report on any hard wood likely to supply the place of boxwood for wood engraving. I was the winner of this medal, which led to some correspondence with Mr. Smith. One of his letters, dated from Dunstable, June 29, 1886, runs as follows:—"My Dear Mr. Jackson—I have sent the block to London so that one surface may be prepared for engraving. I shall then be better able to judge of its quality. It appears to me to be very good, and suitable for engraving. I should, however, not like to try a portrait on a doubtful block, as a face, even of a Fijian king, demands a clear colour and a perfect surface."

The best Yew and Hawthorn are equal to ordinary Box." John R. Jackson, Lymington, Devon.

GROUND OPERATIONS. In the "Week's Work" (see p. 179) Mr. Dunn advises pushing on with digging and trenching. Quite so on light ground, but the trenching of extremely heavy ground is far best left till early spring, for such ground trenched now is beaten down by rain and snow, and in a very bad state for planting in the spring. This I proved by trenching a piece of heavy ground last autumn to receive young Onion plants raised under glass. As time went on I found I had more plants than the ground would hold. A further area of 3 rods was trenched, adjoining the ground trenched in the autumn, and I soon found I had made a mistake in trenching heavy ground in the autumn to receive

* *Agric. Jour. of India*, XII-XIII, July, 1917.

* *Journ. of Botany*, Vol. LV., Oct., 1917.

Onion plants in spring. Those planted on the ground trenched early in March made better bulbs than those planted on the ground trenched in autumn. *C. Davis, Holy Wells Park Gardens, Ipswich.*

CRITICAL REMARKS.—Practically all writers on vegetable growing urge good thinning when in the seedling stage, to ensure proper development. After this season's experience, I question the necessity of so doing with Carrots, at any rate. Owing to lack of labour, my second early batch was left unthinned entirely. They have just been taken up, and a finer developed lot no one need wish to have. If put in an exhibition, many would be passed by as being too big, while the bulk were of average size. As they were being lifted, one could grip a handful of tops and draw up bunches of five to eight specimens. Clearly, had they been thinned very many roots must have been wasted. Spring-sown Onions are another crop that will give satisfactory yields if left unthinned, provided the ground has been well tilled. The maincrop and the late crop of Beet and Carrots are mostly advised to be lifted unnecessarily soon, by which they lose flavour and freshness. Should the earlier sowings have to be taken up to make room for another crop, they should not be put under cover, but stacked on cool ground and covered with their own foliage. The late lots can well be left where growing until it is necessary to remove them to make preparations for another season. The only exception I would make to this rule is when dealing with wet-lying grounds, which would set up rotting. Ashes are sometimes recommended to cover Carrots in store, but a word should accompany such advice, to the effect, that they should be old ashes that have had not less than six months' exposure to the weather. New ashes are too sulphurous. *C. Turner.*

TOMATOS FOR MARKET GROWERS (see pp. 164, 171).—The variety *Kontine Red* requires a lot of heating for general market work, some of the clusters producing ten to twelve good sized fruits. Most varieties of the Sunrise type, grown under ordinary market conditions, produce too many "smallies." An old variety of the right size and quality is *Hillside Comet*. For an outside crop, *Yeale's Leader* has done remarkably well with me this season. *B. Peters.*

AN EIGHTEENTH CENTURY CATALOGUE.—Catalogues such as that referred to by Mr. W. Roberts (p. 152) should give interesting information concerning the so-called "florists' flowers" which were formerly grown. It would be interesting to know, for instance, when the *Pansy* was first recorded as being grown; one reads of its being "raised by seeds, and by off-sets slips of the large, bushy plants, in the autumn or spring, in the beds or borders, for increasing their growth. The varieties may be preserved in this way with safety." (Varieties mentioned but not named as having more than two colours, "as purple blue, yellow, white, improved and enlarged by garden culture." (This in a book published 1807.) One reads also of two species of *Dahlia*, *Dahlia pinnata* (purple) and *D. crocata* (yellow), nowadays regarded as *D. variabilis*, and in addition to an excellent article on the *Dahlia* by Mr. Buonanni, gardener to Lord Holland. With regard to "Smallage," this refers to *Celery*. It may also be of interest to note that *Abercrombie*, in his book published in Capel Street, Dublin, MDCCXXXI., gives 44 varieties of Apples (well approved sorts only), in addition to Crab and Paradise, used for stocks, 5 varieties of Almonds, 9 varieties of Apricots, 4 of *Berberis* (fruits), 16 of *Cherries*, and 4 of *Bird Cherries*, 13 of *Fig*, &c. Apropos of *A. C.'s* "new" methods of storing fruit such as Apples, this old book recommends "carrying them, and disposing in heaps, each sort separately, to remain a week or two to sweat and discharge the watery juices, then wiped dry, and put up into the different divisions and shelves of the fruitery and in boxes or hampers, &c., and then cover the whole closely with clean, dry straw a foot thick to exclude air as much as possible, whereby they will keep much longer in perfection." Generally keep the door and windows closely shut, for the less the external air is admitted the better the Apples will keep." *W. H. Johns.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

Nov. 6.—*Present:* Mr. E. A. Bowles, M.A., V.M.H. (in the chair), Dr. J. A. Voelcker, Dr. W. Bateson, Dr. A. B. Rendle, Messrs. J. Fraser, Ledger, Worsdell, Allard, and F. J. Chittenden (hon. sec.).

Twin Vegetable Marrows.—Mr. J. Fraser showed a Vegetable Marrow with two adnate-fruits, and remarked that a considerable number of similar instances had come to his notice during the present year, the fruits being sometimes separate.

Many-seeded Apples.—He also showed seeds taken from varieties *Duchess Favourite*, *Winter*

primitive character in these genera, for strong shoots usually bear lobed leaves. Specimens of *Morus androsa* shown were almost all lobed, while in many species of *Morus* and *Broussonetia* simple leaves are the rule.

Buds on Roots of Solanum Dulcamara.—Dr. Rendle showed a plant of *Solanum Dulcamara* with a stout root bearing numerous buds all along its length.

LINNEAN.

NOVEMBER 1.—The President, Sir David Prain, F.R.S., drew attention to the important donations of Sir Frank Crisp, Bart., of the complete series of *Linnaea* in 17 volumes, of 14 bound volumes of papers with special index by the Rev. George Henslow, and of the volume de-

FIG. 77. CHRYSANTHEMUM (O. SAGRE) FLOWER WHITE. (R.H.S. Award of Merit, November 10, 1917. (See p. 192.)

Quarrenden, and King of the Pippins, showing seeds in excess of the normal number, 10. Such excess number, up to 20, appears to be fairly constant in some varieties, e.g., *American Mother*, where four ovules in each carpel appear to be normal.

Prothuberation in Rhododendron Flowers.—Mr. Worsdell showed flowers of *Rhododendron* bearing a second flower, a prolongation of the axis through the ovary. He drew attention to the fact that the axis was normally prolonged through the ovary in this plant.

Variation in Leaves of Morus, etc.—He also commented upon the occurrence of both simple and lobed leaves in plants of the genera *Morus* and *Broussonetia*. He suggested that possibly the lobed leaf was a primitive, the entire, a less

posited in the Society's care by Mr. A. Forbes *Seveling* of *Tournefort's Histoire des plantes qui ont essaié aux environs de Paris, 1725*, with the autograph of Bullon on the title-page.

A paper on "The Germination of *Iris Pseudacorus*," *Linna.*, in Normal and Abnormal Conditions, was read by Lt.-Col. J. H. TULL WALSH, F.M.S., as follows:—

Those who were present at the meeting held on November 30, 1916, will remember that Mr. T. A. Dymes told us rather a sad story about his experiences with the seeds of the *Yellow Iris* or *Water-Flag*. He told us that "those (seeds) that fall on to the mud and remain there appear to perish from decay." "Seeds that have not sunk germinate on or near the surface of the water in the latter half of May." "The fate

of those seeds, if any, that sink before germination, has not yet been determined." I am not here to criticise Mr. Dymes. Under the conditions in which the seeds he used were expected to germinate, his results were correct. Seeds floated on deep water in a large glass bottle placed by a window with a sunny outlook behave as described. But the conditions are not normal. *Iris Pseudacorus* is such a hardy plant, so well known in England as a late spring and early summer ornament, that no description and no botanical details are necessary. That such marked changes should have taken place in the germination of the seeds of the Yellow Water-Flag without having attracted the attention of gardeners, seedsmen, and botanists seemed to me very strange—indeed, almost incredible. It is to Mr. Dymes that I owe the seeds which by their growth show, I think quite clearly, that *Iris Pseudacorus* has not been obtaining any "mutations," and may still be trusted to pro-

duced they floated on the superficial water 2 inches deep. During the winter, with its rain, snow, and frost, these seeds sank and rested lightly on the mud. A little later six seeds were floated on water about 10 inches deep; the bottle in which they were placed has been standing on a table in my dining-room in front of a window facing south and south-west. Ponds I. and II. are in my garden.

The first signs of germination appeared on May 19, 1917, in the seeds floating in the bottle—a state of things due, no doubt, to higher temperature in the dining-room, and assisted by a position exposed to our intermittent sunlight. Three seeds germinated on that day, and the other three during the following week. These seedlings throw out a long root, as described by Mr. Dymes. The mass of fibrous roots given off by normal seedlings is quite absent. As these floating seedlings increase in size and weight, they sink. Two, caught in water-weeds, have

ORMSKIRK POTATO SHOW.

OCTOBER 31 and NOVEMBER 1.—An exhibition of Potatoes was held under the auspices of the Board of Agriculture and the Lancashire Farmers' Association in the Drill Hall, Ormskirk, on these dates. The number of competitive entries was in every way satisfactory, and there were many good trade exhibits. The Board of Agriculture showed 120 dishes of Potatoes, which were divided into three sections, viz., those immune from wart disease, others non-immune, and others of a doubtful nature as to the disease. Eighteen classes were devoted to single dishes. Mr. CUTHBERT BLUNDELL, Halsall, and Mr. REGINALD CALLAND each won five 1st Prizes; Mr. JOHN BANKS, Rainford, was successful in three classes; Mr. EDWARD ALTY, Westhead, in two classes; whilst Mr. JOSEPH FARRINGTON, Westhead; Mr. RICHARD ROTHWELL, Aughton; Mr. G. W. BIRCH, Sefton; and Mr. JOSEPH WETHERILL, Clitheroe, each won a single 1st Prize. Messrs. J. and W. BIRCH, Sefton, won the Silver Cup offered for the best collection of immune varieties with 22 varieties of medium-sized, good-shaped tubers.

The Gold Medal offered by Lord Derby was won by Messrs. S. POAD AND SONS, York, for five pebble-shaped tubers of a variety named *The Ally*, and they were awarded Certificates of Merit for the varieties *Majestic* and *Gardner's No. 1* Scabbling.

Mr. CUTHBERT BLUNDELL, of Halsall House, Ormskirk, won the Silver Cup offered by the Comptess of Derby to the winner of the highest number of points, and a second Cup given by Sir Arthur Stanley, M.P., for the most points obtained by a Lancashire farmer.

Obituary.

WILLIAM MARSHALL.—By the death of Mr. William Marshall, V.M.H., which occurred at his home, Auchraith, Bexley, on the 11th inst., horticulture loses an attractive personality that for very many years was closely associated with the work of the Royal Horticultural Society. Mr. Marshall's intense love of plants and catholic appreciation of all the various branches of gardening brought him into contact with gardeners in a variety of ways, as we shall presently show, but he was known to most as the chairman of the Floral Committee of the R.H.S., a position which he held for a quarter of a century. His perfect devotion to the work of the Committee, his unremitting attendances at its meetings, and his frequent journeys to the old gardens at Chiswick, and later to the present gardens at Wisley, with deputations from his Committee, for the purpose of judging novelties in flowers, gained for him the enthusiastic loyalty of the members, who were not slow to recognise the great knowledge he possessed of the various plants which came up for judgment from time to time. A man of strong convictions, Mr. Marshall always had full confidence in his decisions as to the relative values of things, and would not lightly give up a point on which he had made up his mind. He was often credited with standing firm for the Committee's decisions on occasions when they were called in question by the Council. He had good justification for asserting his views, for beyond everything else, the late chairman of the Floral Committee was a floriculturist. He belonged to the older type, who found infinite pleasure in the cultivating of *Auriculas*, *Tulips*, and other "florists' flowers" which are no longer popular with the general public. A lover of *Roses*, one of the great disappointments of his later years was the development in the hybrid *Tea* class of varieties, with large flowers, utterly devoid of perfume. "*The scentless Rose*," as he used to call a variety of this type, was always sufficient to excite his most pronounced criticism.

William Marshall was born on November 20, 1855, at Hackney, but before the attainment of his first year his parents had removed to Upper Clapton, and here he spent the next twenty years of his life. At so early an age as eight years old he showed himself to have inherited

THE LATE WILLIAM MARSHALL, V.M.H.

duce seedlings in mud and shallow water—seedlings which are normal and healthy. If placed in the environment selected by Mr. Dymes, the floating seeds germinate; but if you will compare the seeds grown inside the house, grown in comparatively deep water, with those grown out-of-doors under normal conditions, I think you will agree with me that the former are neither healthy nor normal. The root-system is different and poorly developed, the leaves are pale and lacking in chlorophyll, and the plant is generally deformed. Of the seeds kindly given to me by Mr. Dymes (Dec., 1916) I placed eight (without any choice as to shape) in artificial pond No. I. This contained mud and weeds, was always kept saturated with water when that was necessary, and freed from superficial water when the bowl became filled by rain or snow. Pond No. I. represented the mud at the margin of pond, marsh, or stream. Seven seeds were placed in Pond No. II. This contained the same amount of mud, but when the seeds were

given up the struggle, and are dead. Two lie on the bottom, on a thin layer of mud; they will, I expect, die during the winter. Two are still to be accounted for: I show you these two as dried specimens.

On May 20 seeds in Pond No. II., those lying on mud in shallow water, began to sprout. In course of time seven fine seedlings appeared in that pond. Lastly, the seeds in the mud of Pond No. I began to germinate on June 5. Growth with these seedlings was, at first, slower than with those in the shallow water; but at the end of August the seedlings were as strong and healthy as those in Pond II. The little plants in Ponds I. and II. are now robust, and have passed into a state of rest, which will endure until next spring. I have removed and show you to-night dried specimens from each of the little ponds and from the bottles. A personal examination will tell you better than my words of mine the features which distinguish the normal seedlings from the "bottle seedlings."

his father's floricultural predilections by himself taking part in the Stamford Hill Flower Show, where his father was in the habit of exhibiting Carnations. After concluding his early education, Mr. Marshall was sent to Glasgow University. He excelled in mathematics, and also studied practical chemistry, the latter subject under Dr. Penny. Indeed, he had almost determined to become a chemist, when his father's death compelled a change, and he accepted a position in the offices of Messrs. James Thomson and Co., the founders of the present Orient Steamship Line, where he remained for four years. He later became associated with "Lloyds." After his marriage, which took place in 1859, Mr. Marshall settled in Enfield, Middlesex, and at once began to fill his leisure moments with the culture of Orchids. The earliest instance of his success is marked by the record of a First-class Certificate for *Odontoglossum crispum*, which flowered for the first time with Mr. Marshall, and was exhibited by him at a meeting of the Royal Horticultural Society on April 18, 1865. The achievement of producing the first flower of this most popular Orchid always stood out as one of the proudest in his career. He was particularly fond of a button-hole flower, and the "white crispum" was always the favourite (see portrait figure p. 203). He was particularly successful in these early days with East Indian Orchids, including *Aerides*, *Saccolabiums*, *Vandas*, and *Phalenopsis*—indeed, these constituted most of the Orchids then in cultivation. Cattleyas also succeeded well with him. Two exceedingly fine Orchids bear Mr. Marshall's name—*Oncidium Marshallianum*, a May-flowering Brazilian species introduced in 1866, and *Thunia Marshalliana*, newly allied to *T. alba*. It was introduced from Madras in or about 1870. For many years Mr. Marshall contributed specimens from his collections to the great horticultural exhibitions, especially those which were held at South Kensington, Regent's Park, and the Crystal Palace. The first considerable distinction he won was the Lindley Medal, awarded in recognition of the excellence of a collection of between fifty and sixty plants of *Cattleya* Trinitate varieties, on March 6, 1868; but two years earlier, at the famous International Exhibition of 1866, he had gained the 2nd Prize for ten Orchids, the 1st Prize having been won by Mr. Charles Penny, then gardener to Anthony Gibbs, Esq., and afterwards to the then Prince of Wales at Sandringham. As early as 1866 Mr. Marshall's admiration for British Ferns found expression in a selection of 12 plants which he contributed to the International Exhibition, and for which he obtained the 1st Prize, and he also gained a 5th Prize for twelve stove and greenhouse Ferns at the same show. At the English Fern Conference held at Chiswick on August 25, 1892, he obtained a 1st Prize for four *Polypodiums*, and 1st Prize for the best specimen Fern in the show. In the same year he staged at Earl's Court International Exhibition a collection containing every species but one of British Ferns, and numbers of varieties.

His connection with the Royal Horticultural Society began in 1863, when he was elected a member of the Council on the proposition of the late Mr. Wilson Saunders. He resigned, with the rest of the members, in 1875, as a protest against the South Kensington policy of the adherents. The controversy lasted until 1897, when the South Kensington clique was finally overthrown, and the Society removed entirely from that milieu. In 1903, to celebrate his twenty-first year of office as Chairman of the Floral Committee the members of the Committee entertained him to dinner at the Hotel Windsor, when they presented him with an almost full-length portrait in oils. This portrait now hangs in the Floral Committee room at the R.H.S. Hall. Mr. Marshall's name was included in the first sixty recommended for the Victoria Medal of Honour in 1897, but, in company with Mr. (now Sir) Harry J. Veitch, he refused the honour on the ground that he was a member of the Council, and it was not until 1906 that the medal was accepted. In 1909 he was awarded the Gold Medal of the Vetch Memorial Trust.

Mr. Marshall was a keen entomologist, and had more than the ordinary amateur's knowledge.

He was also a draughtsman of no mean order, and made many delightful sketches of insects and Orchids.

We have so far said nothing in regard to the work Mr. Marshall carried out on behalf of the horticultural charities, but his long and devoted service to the Royal Gardeners' Orphan Fund is certainly to be reckoned amongst his most valuable services to horticulture. He was the Chairman of the Executive Committee of that fund from 1890 to 1900, and it was during his chairmanship that the warrant to use the word "Royal" was secured, mainly by the good offices of Sir Julian Goldsmid, M.P. Whilst charity claimed Mr. Marshall's active sympathies and help, he also desired to provide horticulturists with the advantages belonging to an organisation that encouraged self-help, and it was largely due to his efforts that the foundation of the United Horticultural Benefit and Provident Society, in 1895-6, was safely laid. Now, at a great age, he has gone to his rest, but many will cherish his memory until they also pass "beyond the veil." Deceased is survived by three sons and one daughter. The interment took place on Wednesday last, at Bexley.

HARRY RUSSELL.—Mr. Harry Russell, for the past 15 years gardener and steward to Mr. and Mrs. Howarth, Hanelow Hall, near Nantwich, died on the 1st inst., aged 60 years. Mr. Russell commenced his professional career in the gardens at Shoreham Place, Sevenoaks; was journeyman and foreman respectively at Slugborough Hall, Stafford, and Teddesley Park, Penkridge, and for nine years fruit foreman at Tatton Park, Cheshire. Later he was appointed gardener to the late Lord Hindlip, at Dovegrange Hall, Derby, and subsequently at Hindlip Hall, Worcester. Mr. Russell was a man of exceedingly amiable temperament, and always eager to help others. His remains were interred in Audlem Cemetery on the 5th inst. He leaves a widow and one daughter.

DANIEL SCOTT.—We announce with regret the death of Mr. Daniel Scott, who for the past 36 years was forester on the estates of the Earl of Moray, Dornway, Forres. Mr. Scott was in his 72nd year. He entered the service of the Moray family in 1871, and he did much to improve and extend the fine woodlands on the estates. He enjoyed the confidence and esteem of four Earls of Moray. For fifty years the late Mr. Scott was a member of the Royal Scottish Arboricultural Society, and for several years a member of the Council of that society.

CROPS AND STOCK ON THE HOME FARM.

BASIC SLAG ON LIGHT LAND.

WHERE the soil in arable fields is only about 6 inches thick, overlying chalk, I have found basic slag of great value in promoting the welfare of the crops. Even at the end of the third crop I have found its value as a stimulant, but more, of course, at the end of the second season's crop. An example of rotation is the following:—Oat crop in the current year 1917; the stubble ploughed in before the end of November. Previous to the ploughing, 4 cwt. of basic slag, with a percentage of soluble matter of 32 per cent., is sown evenly over the land. The winter rains and frost thoroughly pulverise the soil. In the spring the land is ploughed several times and sown with Turnips, which are eaten off by sheep; Oats or Barley are then sown, with which is included grass seeds. Trefoil and Italian Rye, at the rate of 6 lb. of the former to half a bushel of the latter per acre. The grass can either be fed off by sheep in June or cut for hay as required. It is in the latter crop that the effects of the basic slag will be apparent. On the thinnest of soils the yield is increased, and all through the season the deep green colour in the grass denotes vigour and a full prospect.

Another example would be Turnips fed off in October, the basic slag sown in November, Oats sown the following February, and the grass in March or early April. Those who have not experienced the effects of this stimulant on chalk soils would be astonished at the improved result in appearance of the grass crop.

I am testing this season the effect of higher grade slag, 42 per cent., as compared with 34 per cent. With these high grades there should be a saving of 1 cwt. per acre, with the consequent reduction in the cost of carriage and labour in applying it. I fear that farmers too often prefer to buy slag of a low grade because it is cheaper, and then condemn the material if they do not experience results equal to the best.

REASONS FOR MILCH COWS.

THE time has come when we have to consider the best food for the cows in milk during the winter, as the nights are too cold and often too wet to allow such breeds as Guernseys and Jerseys to lie out at night. Colds, even in cows, are easily caught, and if neglected are liable to bring on permanent injury, especially in young stock.

When the cows are housed the building should be freely ventilated, but the inlet for fresh air and the outlet for the foul, should be arranged so that the animals are not exposed to direct draughts. Some have an idea that cows in milk do not require, or that it is not an advantage to give them artificial foods including cake, meals, or other food of a concentrated nature. Natural food, as grass, roots, Cabbage, and hay are no doubt very valuable in their way, but an addition of cake is wise, and makes all the difference in the quality and quantity of milk, cream, and butter. Those who make butter know well from results that an addition of suitable cake to the daily feed makes all the difference in the number of pounds per week obtained. I am a staunch believer in high feeding, and I think results justify the outlay.

Many also say the month of November is too early to feed Mangolds to cows; they prefer to wait until February, when the roots are riper and have the saccharine more fully developed, and, naturally, have a higher feeding value. I have never found any injury accrue to the animals by this early feeding, and the roots do not even taint the milk. To avoid any risk of taint the animals should be fed *after* milking, not before, giving hay or cake before milking. The daily ration used here at the present is 35 lbs. Mangolds and 12 lbs. Cabbages, cut in 3 lbs. 5 lbs. long hay, and 3 lbs. Bibby Dairy Cake. Linseed cake is, in my opinion, too fattening for milking cows. The Bibby cake improves the quality of the cream and butter. When milk only is required, brewers' grains and various meals, with decorticated cotton cake, are valuable foods, but where butter is the main aim the ration given above will give good results.

In normal times, crushed Oats would be added, as they are one of the best of milk-producing foods, and especially for butter. Some give Oat straw in the place of hay, but I doubt if it can compare with good quality meadow hay, which, for cows, is superior to field hay, clover, and Rye grass. Oat straw may amuse the animals during spare times.

Some persons chaff the straw and hay and mix the whole together, meals, chaff, &c., but as some cows are apt to gobble up their food quickly, I think, on digestive grounds, hay given long is better for them.

THE EFFECT OF MANURE ON CROPS.

I FEAR some do not appreciate sufficiently the value of manural stimulants upon crops. Farmers who grow the heaviest crops of cereals, roots, or hay, on the contrary, are not stingy in applying manure freely, either directly or to preceding crops, in the shape of farmyard manure, sheep dressing, or artificial stimulants. No field is unworthy of good treatment unless it is water logged and so situated that draining would be too expensive. Some so called poor land is that on the "downs," where there is from 3 to 6 inches of soil overlying chalk. Such thin soils as these, however, are capable of producing useful crops. I get instances every year illustrating the value of manural applications to crops. I will quote two instances occurring at the present time. In the last two years I have failed to grow satisfactory crops of early and late varieties of *Trifolium incarnatum*—although I am not alone in the neighbourhood—owing mainly, I believe, to selecting a piece of land unsuitable as I afterwards found, owing to its want of food and the presence of slugs. The common method is to sow the seed in August on

clean stubble, thoroughly harrowing the surface to bury the seed shallowly. Where the conditions are favourable a satisfactory crop is generally obtained. This year, owing to the harvest being so late, and to the prevalence of so much "brittle" corn, which I know would be a nuisance among the Trifolium in May and June, I selected a clean plot on which superphosphate had been sown for a previous crop. The land was ploughed 5 inches deep, which is all against local custom, harrowed and rolled three times to obtain a solid surface. I resorted to sowing the seed 4 cwt. of superphosphate, 32 per cent., was sown per acre. On this the Trifolium seed was sown, the whole harrowed over three times, and rolled firmly down. The seed germinated quickly; the plant grew rapidly, so much so that the ground is covered with the Trifolium, which is exceptionally deep green. The prospect of a full crop is certainly the most promising I have experienced in twenty years. I attribute the density of colour in the leaf to the action of the manure. In connection with this experiment another fact has displayed itself as thoroughly illustrating the effect of manure. Alongside the Trifolium two acres of Sugar Beet is growing, and although the whole crop is satisfactory, the row next to the Trifolium has made huge tops of dense green leaves and much larger roots than the remainder, but it is at the expense of the Trifolium within 2 feet of the Beet, thus illustrating how absorbent are the roots of this latter plant. The second row displays more colour in the leaves and larger growth than the remainder of the crop, but not to the extent of the first row. *P. W. Wynne, Swannore Park Farm, Bishop's Cleeve.*

ANSWERS TO CORRESPONDENTS.

APPLES AND PEARS SPOTTED: *Hartford* and *V. T.* See reply to *J.* and *H.* under "Pears" in our last issue, p. 194.

BANANAS: *M. H.* We think the lecturer must have meant months when he said weeks. The Banana is propagated by suckers, which are usually from 2 to 3 months of age; the flowering, or shooting, occurs about 7 to 9 months from the time of planting, and about 2½ to 4 months are required from the shooting stage to the development of the full-sized Bananas. These particulars refer to cultivation in tropical countries. In the West Indies, March is the favourite month for planting. The time required for the production of the first crop, from the planting of the suckers, naturally varies with the temperature; at Glenwood, Hawaii, for instance, it requires nearly three years from planting to produce a marketable bunch of Bananas.

CORRECTION. In the note we published last week, p. 190, on the formation of a new Seed Trade Association in Scotland, we inadvertently referred to the firm of Messrs. Bell and Bichenstedt. This firm, however, was dissolved in 1914, and the business now belongs solely to Mr. David Bell, under whose name it is now known.

DRIED SEEDS AS FOOD: *C. F.* The dried seeds of Scarlet Runners and Broad Beans are quite wholesome for eating. In order to have them at their best soak them for twenty-four hours in water before boiling.

GREASE BANDS FOR FRUIT TREES: *E. D.* We do not know the composition of "Ford's Motor Grease," but provided the bands to be used were of material sufficiently stout to prevent the grease from touching the bark, it would not in any case have any bad effect on the trees. If, however, you intend to use ordinary paper bands, it would be better to select one of the fats commonly sold for the purpose, such as "Tanglefoot."

INSECTS ON VINE: *A. S.* The material is insufficient to determine the insect attacking your Australian vine. Gather all the fallen leaves and burn them.

LAWN MOSS: *Patched.* Dressing the grass with Esic slag, as you suggest, would do little to do the grass good, but it would also have a tendency to encourage the growth of Clover. You would do better to apply a dressing of sulphate of iron now, and later on a dressing of

lime. The bad effects of the drippings from trees are very difficult to overcome.

LEAFHOPPERS: *J. E. S.* It is impossible to diagnose the disease from the roots only. The whole plant should be sent.

ANSWERS TO ENQUIRIES: *As the naming of fruits, we desire to oblige our correspondents as far as we can, but the task would become too costly and too time-consuming were there no restrictions. Correspondents should observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones, of two of each variety are sent, identification will be easier. The fruits should be just approaching ripeness, and they should be properly numbered, and carefully packed in strong boxes, cardboard is often smashed in the post. A leaf or shoot of each variety is helpful, and in the case of Plums, Prunes and Nectarines, absolutely essential. An all-over set of labels is known and dated, for which the fruits are sent. By neglecting these precautions, correspondents add greatly to our labour and run the risk of increased delay and incorrect determination. We do not undertake to send answers through the post, or to return fruits. Fruits and flowering plants must not be sent in the same box. Delay in any case is unavoidable.*

LEAFHOPPERS: The Pear was decayed and crushed when it arrived, but it appears to resemble *Beurre Bosc*. It is of no use sending us "ripe Pears for naming, as they decay so quickly as to be almost invariably in a state of pulp when they arrive, the postal deliveries being less punctual than usual.—*H. M.* Broad End Pippin.

—*J. O. S.* 1, Maltster; 2, Gooseberry Pippin; —*C. B.* Pile's Russet; —*D. J.* Goff; 2, Manks Codlin; 3, Lemon Pippin; —*H. F.* Apples, 1, Herefordshire Pearmain; 2, Pear Calabasse; 3, too small and shrivelled; —*Smith.* Apple, Allington Pippin; Grapes, the berries were smashed in transit.

H. G. C., Reading. 1, Harvey's Wiltshire Defiance; 2, Shepherd's Newington; 3, Newton Wonder; 4, not recognised; —*H. W. F.* 1, Doyenne Boussoch; —*T. W. G.* 1, Beauty of Kent; 2, Hambleton Deux Ans; 3, French Crab; 4, Scarlet Nonpareil; 5, Histon Favorite; 6, Bleinheim Pippin; —*J. W. G.* 1, Imperial; 2, *Beurre Jean van Goert*; 2, *Passe Colmar*; 4, *White Nonpareil*; 5, *Reinette van Mons*; 6, decayed; —*L. G. P.* 5, Northern Greening; 10, Orange Goff or Pork Apple; —*W. G. T.* 1, *Carl Tail*; 2, *Court Pendu Plat*; —*F. W. G.* 1, *Beurre Diel*; —*Daniel Pearman, Pooley.* 2, *Beurre Clargene*; 4, *Cullen*; 5, *Strling Castle*; other Pears decayed; —*F. W. P.* 1, *Beurre Bachelier*; 2, *Joséphine de Malines*; 3, *Nec Plus Meuris*; 4, *Marchal de la Cour*; 5, *Beurre Superfin*; 6, *Madame Teyve*; 7, *Dunaldan*; —*T. C.* 1, *Beurre d'Ananias*; 2 and 3, decayed; 4, *Beurre Bosc*; —*Sept.* 1, *Autumn Bergamot*; 2, decayed; 3, *Seckle*; 4, *Louise Bonne of Jersey*; 5, *Winter Nectar*; 6, *Emile d'Heyst*; —*G. B. S.* Pears: 1, decayed; 2, *Marchal de la Cour*; Apples: *Aromatic Russet*; —*J.* 1, *White Westling*; 2, *Brandy's Seedling*; 5, *Galvise Rouge France*; 4, *Alfriston*; 5, *Pear not recognised*.

—*W. J. H.* 1, *Yorkshire Beauty* (syn. *Green-up Pippin*); 2, *Cathead*; 3, *Melrose*; 4, *Lodington*; 5, *Striped Beefing*; 6, not recognised; —*C. P.* *Brandy's Seedling*; —*G. P. S.* *Manmouthshire*. The fruits are not in the best condition for certain identification, as the skins are affected with disease, but we believe the variety is *Marie Louise d'Ecde*.

NAMES OF PLANTS—Correspondents not answered in this issue are requested to be so good as to consult the following number.
C. C. M. 1, Probably *Piptanthus nepalensis*, send when in flower; 2, *Metrosideros Boriemia* (Bottle Brush); 3, *Columnea hirsuta*; 4, *Helix Solanderi*—*W. C. M.* *Acer macrophyllum*.

ONION AND CARROT SEED FOR ONE ACRE: *Essex.* In the ordinary way of drilling Onion seed in rows 14 inches apart, 3 lbs. of seed per acre is required. In that case there need be no thinning of the plants; allow all to grow. A much better method of Onion culture is to sow the seed the first week in February in boxes of prepared soil in a cold frame, and plant out the seedlings when they are large enough to handle, in rows 14 inches apart, setting the plants 4 inches apart in the rows. In that case 4 lbs. of seed should suffice per acre. Seven pounds of Carrot seed will suffice for one acre. If this is mixed with dry sand it will run through the drill easier.

PERIODS OF SEVERE FROST: *Gunner P. Wright.*

The greatest frosts registered during the past 50 years were in the following years:—1879, Nov.-Dec.; 1881, January; 1890, Nov.-Jan., 1891; 1895, Jan.-Feb. The lowest temperatures recorded are:—1879, Dec. 4, 23° at Blackadder, Berwickshire; 1895, Feb. 11, 17° at Bracmar, Aberdeen, and 11.1° at Buxton, Derbyshire.

POTATO PLANTING: *H. B.* The best distance from set to set will depend on the character and strength of the land and on the variety of Potato, whether the latter is of strong or medium growth. Even given the same conditions, experts would differ in their treatment.

We regard 3 feet each way as excessive unless in very exceptional circumstances. Half that distance from set to set, and 2 feet between the rows, should be sufficient in ordinary cases. In regard to one of your questions we prefer to advise you on the cultural points raised rather than express an opinion on the status of this or that authority. The following varieties are all worthy of recommendation: *Midlothian Early* and *Duke of York* (early), *British Queen* and *May Queen* (mid-season), and *King Edward VII.*, *Arran Chief*, *Dalhousie*, and *Windsor Castle* (late).

PUPA FROM FRANCE: *M. S. A.* The chrysalis is the pupa of the Orange Tip Butterfly.

SOUVENIR DE LA MALMAISON CARNATIONS: *C. T.* June and July are the best months to layer "Malmaison" Carnations; September is too late to get the plants well established before winter. The plants require very careful treatment during the autumn and winter, as the blooms are long in expanding; very little water is necessary, and no stimulants should be given. Your general treatment appears to be correct. Top-dressing or re-potting the older plants is necessary for early flowering in spring. Two houses are necessary, as these older plants require a temperature from 5° to 10° higher than young stock to flower early. The latest plants should be grown in cool conditions to retard them. Spraying with salt and water is safe during the summer, but should not be done during the winter; this possibly is the chief cause of your blooms damping.

WALNUTS: *J. L.* No "insect" is to be found in the specimens sent. Is it possible that rooks have caused the damage?

WATERCRESS: *P. and C.* There appears to be no fungous parasite in the Watercress plants. Their appearance suggests injury caused by some insect or other form of animal life. If which is, indeed, and any specimens of the "insect" is kept, send them for identification. —*R. Z.* The approach of winter is not the best time to commence Watercress growing, nor are seeds the best method of raising a good crop of the most suitable varieties. If you wish to raise the plants from seeds, the latter should be sown in March or April in moist soil, afterwards transplanting the seedlings to boggy trenches, or, better still, to slow running and shallow streams of clear water. Propagation by cuttings or division is one of the simplest methods of increase. The cuttings soon rot in muddy soil, provided the water is not stagnant, while portions of the plants with a few white roots attached may just be thrown into the water and allowed to take care of themselves. Cuttings or divisions may be planted now or in spring. What is known as "brown" Cress thrives best in spring water that has come through a chalky sub-soil, while "green" Cress generally does best in river or canal water. In all cases the water must be very slow running, and may vary in depth from a few inches to a few feet. In large beds weeds and scum must be kept down, and it is generally wise to clean out one-half of the beds one year, and the other half the following year, where large areas of Watercress are cultivated for market.

A REVISION OF THE RED CURRANTS.

THE nomenclature of the Red Currants has long been in a state of confusion. There are many reasons for this, and one is that no one seems to have thought it worth while to publish an accurate botanical description of so unimportant a thing as a Currant. A second cause is, I fear, the practice that we nurserymen have had in the past of retaining plants. I do not wish to be the one to cast the first stone, and will leave this matter here, as I think any such practices are now almost universally reprobated. A third and important cause of confusion is that so many of the Red Currants reproduce themselves almost true from seed. It is quite possible, therefore, that many "new" seedlings have been introduced in perfect good faith, where the raiser did not happen to know Currants well, which were but reproductions of known varieties. The last difficulty is that the fruits of Red Currants are in many cases so much alike that it is quite impossible to discriminate between them without knowing all the plant characters. The growth and habit, coupled with the very distinct characters of the flower, are the best means of identifying the different varieties.

With the object of tackling the problem of nomenclature, I collected in 1912 all the varieties I could procure from gardens and nurseries in England and from America and the Continent: these amounted in all to over seventy. It was soon demonstrated that there were many more names than varieties, and further, as expected, there was considerable doubt as to the identity of certain sorts. It has been an extremely difficult matter in some cases to decide what is the original type. In the Red Versailles, for instance, plants from six sources gave three distinct sorts. To settle this matter, description and figures, where available, were referred to,

and weight given to the source of plants. It is probable, for instance, that an established nursery in Paris would be more likely to have the true Versailles than an English firm that may not have taken much trouble on the subject. Contrariwise, an English variety still in the hands of its reproducer, would presumably be true to name. I fear that in some cases I shall be told that the variety I have decided upon is not the "true" thing, and, of course, it may be so; where, however, all is confusion someone must make a clearance. I shall not here go into

R. vulgare. A further character is that the flowers and fruit bunches hang downwards, thus distinguishing them easily from the rubrum varieties, of which the flowers are always held out stiffly at right angles. The foliage is generally rather thin, yellowish, upward-folded more or less, and almost hairless. R. rubrum varieties are very distinct in all characters. The flowers are bell-shaped without the fleshy ring, held horizontally in the young stages, the foliage lax, and with much more substance than R. vulgare, and generally densely hairy beneath. The fruits

From the "Journal of the Royal Horticultural Society."

FIG. 78.—WINTER SHOOTS OF CURRANTS.

1. Ribes vulgare. 2. R. petraeum. 3. R. rubrum.

details of the history of the Red Currant, as I have treated of it as some length in the current *Journal* of the R.H.S. It will be well, however, to state that three species have entered into the constitution of the garden Red Currant as we know it to-day, viz., Ribes vulgare, R. rubrum, and R. petraeum. The flowers of these are all very distinct. R. vulgare has a very open, flat flower, green, with or without a red eye, and showing a distinct fleshy ring around the pistil. This ring is a constant character, and serves to separate at a glance all derivatives, and even hybrids of

are on stiff, wiry stems, held on one side of the bunch, thus distinguishing them from true vulgar varieties, which, owing to their lax pedicels, swing freely all round the bunch. The true Raby Castle is a pure rubrum. R. petraeum has given us but few varieties, of which Prince Albert and the Seedless Red Currant are typical. The stout bullate leaf, red shoots, remarkable claret-red flowers and late habit of starting and ripening, are very noticeable in all its descendants. No one looking over a bed of varieties could fail to pick out this type.

The "Rings" section contains those large-headed and fruited sorts, of which Versailles, and also Lady's Palfrie are typical. These are the so-called *R. vulgare macrocarpa* forms, as they bear true "vulgare" flowers, though the thick leaf of a milky-green colour is a new character. It will therefore be convenient to call these the "macrocarpa" section. A common character these all show in varying degrees is the habit of going blind, and the stout shoots breaking off when overloaded or when growing in windy places.

In respect of the characters used in description, it may be as well to point out that the apparent petals of the flowers are really the sepals; the petals are very small and abortive, and generally wedge or T-shaped. The fleshy ring of "vulgare" is alluded to as the "ring." The winter wood characters will all be quite obvious except the angle taken by the bud, which may be close pressed to the shoot or leaning away at an angle. These are called "bud close" or "away," as the case may be. I have not described the "flavour" or degree of acidity, as it is quite impossible to get all the fruits at identical stages of ripeness, and such phrases as "rather acid" convey no information.

In giving synonyms I refer to the names under which I received the varieties, which may not always be synonyms in the true sense, but often errors of naming. I desire to thank many of my fellow-nurserymen for the help they have given me in forming my collection, and also many other friends who have furnished me with material. It is with the greatest reluctance that I have altered any name, preferring to let an established one stand, even if not the first given, rather than cause fresh confusion by a too strict adherence to the rules of nomenclature.

THE BABY CASTLE GROUP.

In this group are the varieties which show the influence of *R. rubrum pubescens* very strongly; the soft, downy leaves are characteristic. Baby Castle is a true rubrum, whilst Houghton Castle (see fig. 79) by its "ring" round the pistil, indicates its descent from rubrum vulgare.

Baby Castle (rubrum). Syn. American Wonder, Red Versailles, Dutch, of some.

Flowers.—Crescitate, without ring, petals markedly wedge-shaped, sepals washed with light red when young, rachis with thick curling hair. Flowers before leaves.

Leaves.—In young state pale yellowish-green tinged with brown, when fully grown, soft yellowish-green, held flat, densely hairy beneath.

Fruit.—Bunch medium length, rachis yellow, downy, pedicels fairly short, held to one side. Ovary bright red, does not turn dark on the tree, making a bright sample in the basket. Prolific.

Season.—Rather late. Buds.—Winter state, buds rather small, thin, and pointed much away, markedly hairy.

Growth.—Upright and of moderate vigour.

Origin.—Raised at Baby Castle. Mr. Shortt, gardener at Baby Castle, writes in 1860 that it is "frequently confounded with Houghton Castle, a later production. . . . Original tree still at Baby Castle." The present head gardener at Baby was good enough to send me specimens from the trees still grown there, which confirm the description above. Houghton Castle is very often sold for this Currant, but it is quite distinct in growth, being of spreading habit. Market gardeners often say they dislike Baby Castle as it turns dark red. In these cases they have got Houghton Castle in error.

OLONTOGLOSSUM (rubrum x vulgare). Syns. Woolly Leaved, Mallow Leaved, American W. B., New Red Dutch, Red Grape, R. B. L., Houghtonium (Janex), May's Victoria, Defiance.

Flowers.—In bud, slight ring visible, petals less than sepals, but Baby Castle, sepals slightly red, rachis remarkably downy.

Leaves.—In young state silvery-white, not

yellow and brown tinged as in Baby Castle; when full grown, soft yellow-green, densely woolly beneath, very like Baby Castle in this stage.

Fruit.—Bunches long, stem (before berries start) long, rachis green, stiff, hairy, berries medium, soon turning a dark, dull red. Prolific.

Season.—Mid-season. Buds.—Winter buds medium size, pointed, away, a little hairy.

Growth.—Very strong and spreading.

Origin.—Rather doubtful, but probably from Houghton Castle, near Hexham. Introduced about 1820.

Often mixed with Baby Castle, but can be picked out in spring by the colour of the young foliage; in flower by the presence of a "ring"; and by its spreading habit, contrasting with the upright growth of Baby Castle. *E. I. Bouquard.*

(To be continued.)

ORCHID NOTES AND CLEANINGS.

LAELIO CATTLEYA SIR HENRY WILSON.

MR. MUSK, gardener to Lieut.-Colonel J. F. Laycock, Wiseton, Bawtry, Yorkshire, sends us a showy flower raised at Wiseton, between L. C. Henry Greenwood (C. Hardyana x L. C. Schilleriana) and L. C. bletchleyensis (C. Warszewiczii x L. tenebrosa). Cattleya Warszewiczii enters twice into the composition of the hybrid, and takes a lead in its large size and form, but the L. C. Schilleriana (C. intermedia x L. purpurata) in L. C. Henry Greenwood is evident in the elongated front lobe of the labellum. The flower, which is 7 inches across, has white sepals and petals suffused and veined with light purple. The exterior of the tube of the lip is coloured like the petals, the interior being white, tinged with yellow, and with purple lines running into the reddish-purple front lobe, which shades off to lilac towards the margin.

ODONTOGLOSSUM ARIDENTIFLORA

Is this pretty new hybrid raised between *O. ardentissimum* (Pescatorei x crispum) and *O. Dora* (Lambianum x Pescatorei), the next

form, broad petals, and lip characteristic of *O. Pescatorei* are marked features, and in the present form it may be likened to a very fine and prettily blotched variety of that species with the addition of a firmer texture to the flower, which is obtained through *O. Rolfeae* (Harrayanum x Pescatorei), which also brings in the third *O. Pescatorei* influence. The flower is white tinged with violet at the back, the sepals having a cluster of vinous-purple blotches and the petals a central group of irregular spots of the same colour. The broad lip has three purple blotches in front of the yellow crest. The novelty is sent by Mr. E. W. Thompson, gardener to Philip Smith, Esq., Haddon House, Ashton-on-Mersey.

BRASSIA BRACHIATA.

A FINE inflorescence of this Brassia is sent by Messrs. Jas. Cypher and Sons, and well demonstrates the character given it by Lindley, who described the species from specimens collected by Hartweg in Central America for the Horticultural Society about 1842, as the finest species of the genus. The spike bears thirteen flowers, the long, slender sepals extending over a foot from tip to tip. The petals are shorter than the sepals; both sepals and petals are greenish-yellow, with dark purple blotches on the inner halves. The broad lip is cordate in front and narrower at the base; the colour is pale yellow, with raised olive-green spots. The plant is evergreen, and thrives in an intermediate house or ordinary plant stove.

CATTLEYA APPLETONI.

MESSRS. JAS. CYPHER AND SONS send us flowers of this interesting cross between *C. elongata* and *C. Dowiana aurea*, taken from a spike of fourteen flowers. The blooms, which have some resemblance to those of *Laelio-Cattleya elegans*, have mauve-tinted sepals and petals and deeper mauve lip, the front lobe of which is violet-purple. *C. elongata* was the seed-bearer, and the hybrid approaches that species in form.

LETTERS FROM SOLDIER-GARDENERS.

IN EGYPT.

URING the autumn months of last year I had the opportunity of seeing some of the gardens and parks of Cairo, owing to a trouble with my leg, which, with excellent medical attention, recovered sufficiently for me to be sent from a base to a convalescent hospital in Cairo. To be there after a period of strenuous duty upon the desert gave me great pleasure. I was anxious to see the agricultural crops of the Nile Delta, and to find out what vegetation comprised the embellishment of the gardens and parks from the horticultural point of view. To a limited extent I was able to satisfy my curiosity, although the railway only skirted the eastern margin of the Delta.

I was impressed with the productiveness of the land and the prospective yield of the crops. Owing to the absence of rain most of the crops are cultivated by irrigation, which is easily performed by the natives in a methodical and systematic manner. They are aided by an abundance of water, and the land is naturally a vast plain.

A good Cotton crop had been nearly harvested. On one plantation of Cotton the old stems had been left, and a crop of Peas, which were then a few inches high, were apparently going to be supported by the stems. The native growers do not follow this practice; the old Cotton plants are usually pulled up and burnt, a procedure recommended by the State to minimise the ravages of the Pink boll worm, which is a menace to the Cotton plant. Large fields of Maize were frequently seen; some of these were being harvested, and others were in different stages of growth. Sugar cane grows luxuriantly and in quantity. Matured cane is stripped of its leaves and sold by vendors in the streets of Egyptian towns. Tomatos, Aubergines, and Capsicums produce their fruits, and require but little attention beyond watering. I think with more attention Tomatos could be obtained equal in quality to those at home, but at present they are inferior in every way. Cucumbers, Melons, Gourds, and Vegetable Marrows, as well as Onions, Leeks, Beets, Carrots, and Cabbage, are cultivated successfully, with table qualities equal to our home-grown produce. I did not see any Potatoes growing. I should have thought young tubers could have been procured at all times throughout the year in a climate like Egypt possesses. Those I have seen and partaken of are not of the quality one would obtain at home. I attribute it to the great heat and dry atmosphere that prevail during the greater part of the year, which impoverishes the tuber, consequently great care is necessary with them after they are taken from the ground in storage and transit. The Sweet Potato (*Ipomoea batatas*) was plentiful, and formed an agreeable dish. Personally, I like it, but to some palates it does not fill the place of the homely tuber. Large areas of land were being tilled, I assumed, for cereals, with oxen teamed to primitive implements. Nevertheless, the work of ploughing, cleaning, drilling, or planting is ably carried out by the natives, and good crops are obtained. The rich alluvial lands, combined with an ample water supply from the great and ancient Nile, and a climate of perpetual sunshine, are conducive to the growth of numerous food products.

THE PUBLIC GARDENS.

In the well kept public gardens many well-known exotic plants are to be met with growing luxuriantly and flowering profusely from their short-jointed growth ripened under the glare of a tropical sun. The floriferousness of Bougainvillea glabra was remarkable. I saw it used in forming arches and covering fences where it grows naturally to a large size, and the beauty

of its bracts is enhanced in the radiance of the brilliant sunlight. *B. spectabilis* was planted at the base of a Cypress; its growth encircled the Conifer, and festoons of its brick-red bracts contrasted admirably with the deep green of the foster-tree. This species is rarely met with in British gardens, attributable probably to the difficulty of flowering it.

Bignonia venusta apparently is thought much of by the frequency it is seen planted. The most magnificent sight I had of this climber was provided by a specimen covering a mass of masonry, where it could develop to its fullest extent. It literally draped the column with its mass of apricot-coloured blossoms. Another clothed the bole of a Date Palm. At Colbury House, Totton, Hampshire, the residence of Mr. C. Louch, where I had the privilege to be head gardener prior to the outbreak of war, we grew this climber in a large house, where it was planted out, and in December we were amply repaid by a wealth of bloom. *Solanum Wendlandii*, another South American climber, finds a home in Egypt. This, too, is grown at Colbury, planted out in the spacious conservatory; the flowering shoots used to be untied and allowed to hang down, being supported with thin twine from the roof-trellis, and for the greater part of late summer the specimen was a pleasurable sight. It also lends itself to pot culture, as is generally known, many of us being familiar with the superbly grown pot plants exhibited by Mr. Godfrey, of Exmouth, at the Royal Horticultural Society's meetings. A plant I took to be a huge *Rivina aurantiaca* was, on closer examination, unmistakably a *Solanum*. It had similar orange-coloured fruits, borne on racemes characteristic of that plant, but appeared to drop its basal fruit easily, thus detracting from its appearance. *Ipomoea rubrocorollata* merits its place, and is, as one would suppose, much finer than in Britain. Often its flowering period is retarded by the wet and cold of late summer. *Thunbergia alata* shows its golden flowers to advantage, growing and twining round a shrub less showy. The agreeable perfume of *Jasminum grandiflorum* is wafted on the cool air of the starlit Egyptian nights, which, like the days at this time of the year, are ideal and restful, after the excessive heat of the past month. *F. Gooch, Egyptian Expeditionary Force.*

ON INCREASED FOOD PRODUCTION.

LIFTING CARROTS AND BEET.

THE remarks on p. 153 by Mr. Dunn concerning late crops should, I think, receive further attention, and be applicable to the later sowings of Beetroots. His note implies that Carrots may be taken up too soon. I believe that the roots of both Carrots and Beets are lifted too early in many gardens. It seems to have become the practice of gardeners, as well as amateurs, during the past few years, to store these vegetables in October, and even early in that month. Except for the earliest sown batches this is quite unnecessary. Both kinds

of vegetables are hardy, and I see no good purpose in treating them as being half-hardy. But they should not remain late in the ground where the soil is very wet, as they would be liable to splitting, and become coarse; and they must, of course, be lifted if the ground they occupy is urgently needed for a subsequent crop. In light soils the late batches of Carrots and Beetroots may be wintered where grown, drawing a little soil around the latter roots in the event of severe frosts. *C. Turner.*

POTATO AND ONION CROPS AT HESTON.

FOR several years the Heston Horticultural Society has encouraged its members to produce heavy crops of Potatos by arranging annual competitions. In one competition the heaviest crop from a row 2½ feet long wins, while in

[From sketch by Miss F. Bonyard.]

FIG. 79.—CURRANT HUGHESON CASTLE.

(See p. 209.)

another competition the grower must excel with one plant grown on one square yard. This year the entries were good, and all competitors had to grow The Chapman from the same seed stock, place the sets 18 inches apart, and allow 2½ feet between the competitive row and the next rows. The average crop from eighteen rows was 51½ lbs. All the crops were lifted the same day and carefully weighed in the presence of a committee. The separate results were—Mr. W. Morris, 74½ lbs.; Mr. G. Weston, 72 lbs.; Mr. T. Weston, 71½ lbs.; Mr. B. Mascheld, 65½ lbs.; Mr. J. Harmer, 62 lbs.; Mr. A. Dyer, 59½ lbs.; Mr. H. Chandler, 59 lbs.; Mr. C. Lewis, 54½ lbs.; Mr. S. A. Cragg, 53½ lbs.; Mrs. Mascheld, 53½ lbs.; Mr. P. Walker, 51 lbs.; Mr. A. Brett, 46 lbs.; Mr. P. A. Cragg, 40 lbs.; Mr. A. Crier, 39 lbs.; Mr. W. G. Lobjot, 38 lbs.; Mr. C. Cox, 35 lbs.; Mr. A. J. Robbins, 32 lbs.; Mr. E. Gladman,

23 lbs. It will be noticed that the best crop was just about $\frac{3}{4}$ times the weight of the one lowest on the list.

There were fourteen entries in the "one set per square yard" competition, and here Mr. S. Weston came out top with a crop of 11½ lbs.; the other weights were 11, 10, 9, 8½, 6, 6, 6, 6, 4, 4, and 2½ lbs. respectively, an average of 7 lbs. per root.

A new competition was one in which a prize was offered for the heaviest crop of Onions from a 12 feet row. In this, Mr. Percy A. Cragg led with 32½ lbs., closely followed by Mr. G. Weston with 30½ lbs. Other weights were 27½ lbs., 27 lbs., 18½ lbs., 18 lbs., 17 lbs., 16½ lbs., 16 lbs., and 14½ lbs., the average weight per row being 21 4.5 lbs. C. H. C.

THE BREAKING UP OF GRASS LAND.

THE leading article on this subject on p. 190 should do much to convince any waverers (and there are not a few) as to the advisability of breaking up unprofitable or even moderately good grass land. I have ample opportunities of observing how little benefit to the nation much of the grass land is now, being chairman of an advisory committee in this county, which is charged with an order to add 90,000 acres to the existing arable land. It is strange to see how some cling to their pastures, when it can easily be proved to them that much of their grass land does not produce more than half a ton of hay per acre, the hay being worth only £2 15s. Under good arable cultivation a first season's crop of Oats would return the grower at least £9 per acre, less the cost of production, and this is a low estimate.

In this county there were not many failures; probably the most were not evident during the harvest after Mr. Middleton's report was made. Where the Oats were a heavy crop many plants were laid owing to heavy showers and high winds. Oats are quite the best of cereals to grow on newly broken up grass land, because they grow away more quickly than any other cereal, provided chemical fertilisers are used liberally. Wireworm does not injure the plant after the second pair of leaves is formed.

Where Oats are to be sown it is better to defer the ploughing of grass land until the end of February or early in March, in order that the sowing may be done promptly. Wireworm has not then time to ramify through the roots of the grass before the Oat plant has grown out of farm's way by the aid of liberal manuring.

The past season's experience will teach farmers where they erred in methods of cultivation, especially with Potatoes. The farmer was not always to blame. In many cases hurried decisions were arrived at to put in certain crops, and there was not always time for due preparation. Earlier ploughing would have enabled the sward to decay more promptly—an advantage to the Potato crop. The advice given as to the summer fallowing of strong land is good, especially if it is foul, thus enabling cleaning to be done. This summer was a bad season for this kind of work, August being very showery.

Nowadays, too, there does not seem time to follow land much. Many farmers prefer to use a catch-crop of some sort, such as Mustard, Vetches, or Rape. Still, the fallowing of land in the summer, followed by a dressing of farmyard manure, generally brings good Wheat the following year. E. Molyneux.

AN ALLOTMENT GROWER'S EXPERIENCE WITH POTATO GREAT SCOT.

At the beginning of the present year the Parish Council of Ludworth decided to take over a small portion of a field for the purpose of allotments. My plot, which measured 300 square yards, was the very worst of the lot, being waterlogged, and a large portion of it was under water to the depth of about 1 inch. I dug a trench 3 feet deep from corner to corner, and found an old drain to take away the water at

one corner. Then I found a strong spring, and had to trench again. The other allotment holders formed a ditch down the south side, and I got all the water again, and had to trench that side as well. But in the long run it proved a blessing, for I made a well there 4 feet deep, and was never without water during the hottest part of the year. I found a difficulty in getting seed of Great Scot, but a friend sold me ten tubers which weighed just on 2 lbs. I placed them on the floor of my greenhouse to sprout, and afterwards cut the ten tubers into 45 pieces, each containing one eye. I got about five pieces from each Potato. These I planted in 5 inch pots in good soil, and plunged the pots in a frame which I had just emptied of Violas. I dug a trench across the allotment about 22 yards long. I had no manure except a little dry poultry droppings, and these I scattered at the bottom of the trench. I planted the Potatoes about the first week in May. A single dusting of sulphate of potash was used. Lord Howard offered a cup valued £10 for the heaviest 15 Potatoes grown on allotments belonging to him. The hauls of my Potatoes by this time were 1½ yard long. I removed the soil at one root, and the first potato I encountered weighed just over 14 oz. On the morning of the show at Glossop, Sept. 29, I lifted the crop, and got together 15 Potatoes of a total weight of 12½ lbs. I won the cup, but it was only by one pennyweight, though I must add my runner-up had to dig the whole of his allotment of 300 square yards, while I dug up a 22-yard run only. The proudest moment was when I weighed the produce of that one row, and found that I had got 114 lbs. of good potatoes, that is, 57 lbs. from each pound of seed planted. H. G. Healy, Ludworth.

MAY QUEEN POTATOS AT BECKENHAM

ON ground occupied by Sweet Peas in 1916, Mr A. Scutcher, The Gables Gardens, Wycombe Road, Beckenham, planted May Queen Potatoes. Thirty-six sets were planted, 16 inches apart, on an 18-yard run. The crop weighed 205 lbs. when lifted, giving an average of 5 lbs. 10-29 oz. per root. The smallest yield from one root was 2 lbs.; the highest was 10 lbs. The Potatoes were sprayed twice during July, and the crop was lifted on August Bank Holiday.

COOKING PUMPKINS.

ONE of the best methods of cooking Pumpkins is to cut the fruits into moderate-sized cubes, put them in a covered fireproof vessel with some butter or fat (no water), and a ravigotte of chopped Butter and Parsley, with perhaps a Bay-leaf or a tiny sprig of Winter Savory; put in the oven and let the fruit stew in its own juice. Remnants may be used to make puree soup, for what is there better than a good Pumpkin soup? Against jam and pies do the sugar and flour positions forbend. H. E. D.

ALLOTMENTS AT BIRMINGHAM.

AN exhibition of allotment produce was held in the Birmingham Town Hall on the 7th and 8th inst., inaugurated by the Parks Committee under the management of Mr. W. H. Morter, Chief Officer of the Parks Department. Upwards of 1,200 prizes were offered to allotment-holders throughout the thirty districts of Birmingham.

About two hundred dishes of Potatoes were exhibited by the Board of Agriculture from the trial grounds at Ormskirk. The trade was represented by exhibits from Messrs. Sutton and Sons, Ed. Webb and Sons, Dickson and Robinson, Allwood Bros., Gunn's, and Simpson and Sons. Medals and Certificates of the Royal Horticultural Society were awarded to these firms, and also to some of the exhibits in the competitive classes. The local Parks Department contributed an excellent collection of vegetables.

Since the beginning of the present year the Birmingham Parks Department has provided about 6,500 plots to allotment-holders. J. S.

THE KITCHEN GARDEN.

By J. DUNN, Foreman, Royal Gardens, Windsor

ASPARAGUS.—If a sufficient number of strong roots are available a supply of forced Asparagus may be had throughout the winter with little trouble and expense. The crowns are quite ripe, and a start with forcing may be made. A brick pit is best for the purpose, and a new hotbed should be prepared from Oak-leaves, which will produce a mild and lasting warmth capable of forcing several batches of roots. If the temperature of the bed should fall too low for forcing, shaking up the leaves and mixing with them a quantity of fresh material will correct matters. When the bed has been made firm decayed manure should be sifted over the surface and a thin layer of sieved leaf-soil placed on the top to prevent the roots from coming into direct contact with the manure before growth commences. The roots should be placed closely together and covered with fine leaf-mould, which may be washed in amongst them, using water warmed to 80°. In a few days the young shoots will be sufficiently advanced in growth to require a covering of fine, sieved leaf-soil to the depth of 4 inches. By excluding the light the leaf-mould will blanch the shoots and cause much quicker growth. In 8 or 10 days afterwards the Asparagus will be ready for cutting. When Asparagus-roots are lifted from the beds for forcing they should be placed in the forcing-pit at once.

PARSLEY.—All overgrown and decaying leaves should be removed from plants which are intended to stand the winter in the open garden. The young growth produced after this date will be much harder than that produced early in the season. Hoe the soil between the rows on frequent occasions. Plants in cold frames should be treated in the same manner, and the lights kept off until frosts occur.

SPRING CABBAGE.—Examine the rows of Spring Cabbage, and if slugs are present dust with hot lime in the early morning and again a week later. Hoe the ground and fill all vacant places in the rows with as little delay as possible. Plants which are still in the seed-bed should be transplanted at once in a border where the soil is not over-rich, allowing a space of 4 inches between the plants each way.

GREEN HERBS IN WINTER.—Place roots of Mint and Tarragon on a gentle hotbed to furnish supplies of green shoots. Sorrel and Chives are easily forced in this way. A good ball of soil should be left on the roots, placing the plants quite close together on a gentle hotbed.

POTATOS.—All seed tubers of early Potatoes should be selected and placed on trays with as little delay as possible. Many of the early varieties are producing shoots, and if not carefully placed on trays at once much injury may be done, as the growth is almost certain to become drawn. A good shed is suitable for sprouting Potatoes, provided frost is excluded. All Potatoes in stores should have sufficient covering placed over them to protect them from frost. It is good practice to secure a quantity of dry material for this purpose and keep it ready for use.

FRUITS UNDER GLASS.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

VINES GROWN WITH OTHER FRUITS.—Good results can be obtained from vines and fruit trees in houses not specially given over to their cultivation. In a moderate-sized house it is often possible to plant a vine at one end and allow it to run over the roof. Such a house here, used in the winter to store large scented-leaved Pelargoniums and other decorative plants, contains a good type of Black Alicante vine.

which has produced for many years past fine crops of Grapes, some of the bunches this season weighing more than 5 lbs. No proper border was prepared for the vine, which was merely planted in one barrow-load of loam. The house has a west aspect and a span-roof, the walls at the sides being about 3 feet high. The bunches are usually all cut by the time the Pelargoniums are stored, and there is no trouble with damping in the berries if a steady fire is kept going. Many glasshouses could be turned to account in this way, and a saving of labour and expense effected. I know of a span-roofed conservatory in the Midlands in which Figs are planted at one side and thinly trained on the roof to allow the light to enter the house. What is applicable to vines and Figs applies also in a lesser degree to Peaches and Nectarines. Attacks of green fly and other insect pests must be guarded against when fruit trees are cultivated in houses with other plants.

FRUIT TREES AS DECORATIVE PLANTS.—It is surprising that greater use is not made of Peaches and Nectarines as decorative plants in large tubs and pots during the spring. They may be used in conservatories in which early bulbs and other spring flowers are grown. With a proper amount of ventilation it is possible to secure fairly good crops of fruit. Suitable varieties for the purpose are Peregrine and Dr. Hogg Peaches, and Humboldt and Early Rivers' Nectarines. Early Rivers' and May Duke Cherries might also be tried; the pollen of May Duke would set the fruits of Early Rivers. Even if the crops of fruit are not so large as could be desired the plants will be highly decorative when in flower. I saw an admirable illustration of this method in a garden on the Continent, where, in a span-roofed house, several Peach and Nectarine trees were furnished with good crops of fruit. The trees were all growing in large tubs, and had made good growth.

FRUITS OF PASSIFLORA.—The fruits of both *Passiflora edulis* and *P. quadrangularis* may be used for dessert; the former species does not require so much warmth as the latter, and it is distinctly ornamental when in fruit. The one essential in fruiting these climbers is to see that the flowers are pollinated, which often has to be done by hand. Keep the young shoots stopped when the fruits are forming to cause them to seed.

WINTERING POT TREES.—Where no attempt will be made to exclude frost from houses in which pot trees will be wintered, measures must be taken to safeguard the pots against being cracked during severe frost. One method is to secure sufficient dry stable litter to place between the pots and over the surface. Another is to plunge the pots in cinder ashes from the stove-holes. In an absolutely cold house, and where the growth is normal, the latter system may be adopted. The soil in the pots will keep moist, and the pots may be plunged as close together as possible, thus saving room and necessitating the use of fewer ashes. Our late Plums are plunged in this way until the flowering period arrives, when they are removed further apart. When litter is used there is a possibility of the soil becoming dry at the roots.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to the Hon. ARTHUR J. DAVEY, Abbeots Wood, Godingham, Surrey.

CHERRIES.—In planting both sweet and Morello Cherries, choose well-drained, leamy soil, containing plenty of old mortar rubble or lime. Plant firmly, and do the work in dry weather. Cordun trees should be set 2 feet apart, those of fan shape, 15 to 20 feet; bush trees and pyramids 9 to 12 feet, and standard trees for orchards 15 to 20 feet apart. Established trees may be pruned and trained from now onwards. Cut out all dead spurs and prune the new shoots to about three buds. If the trees have been summer pruned, the growths will require very little shortening at this operation. Train in the shoots of the current season evenly, and use plenty of loose ties to keep them in position.

PRUNING.—Take advantage of fine, mild weather to prune Pear and Apple trees. Bush

trees should be thinned freely and the branches trained regularly apart. There will be no long shoots on trees that were summer pruned, and those that have reached their size limit should be pruned hard. Mature trees need root-pruning occasionally in order to restore the balance of growth between roots and branches. Endeavour to obtain fruiting wood in all parts of the tree, for where the fruit sets in clusters irregularly it is never of the finest quality. Exhausted spurs on very old trees should be thinned and the development of fresh ones encouraged. The pruned spurs will break thickly and strongly into growth in the spring, when they should be thinned to a suitable number. Some trees naturally grow shapely and require much less pruning into shape than others.

WALL TREES.—Trees growing on walls or other supports need similar treatment to that described above. When the pruning has been done and the trees cleaned, the shoots may be either nailed or tied to the support. All old ties should be removed, as these may contain insects or the larvae of insects. Following the work of training and tying the trees, a thin layer of soil should be raked off the border, in case grubs or caterpillars are harbouring therein. After this, a slight dressing of lime or basic slag should be used, and a little fresh soil or ashes scattered over the surface to provide a clean substance for walking on. The part of the border containing the roots should not be dug with a spade, but loosened lightly with a fork. Vegetables, etc., should not be planted nearer than 5 or 4 feet from the wall. If insect pests are detected, cleanse the trees thoroughly. American blight require care and vigilance to stamp it out, as it spreads rapidly to other trees.

THE ORCHID HOUSES.

By J. COOPER, Gardener to Sir JEREMY COLMAN, Bart., Gatton Park, Reigate.

DENDROBIUM.—The majority of plants of *D. Phalaenopsis*, *Schubertianum* and its varieties are in bloom. The flowers may be kept in good condition for several weeks if the plants are grown in a dry, intermediate temperature. The flowering should not be allowed to exhaust the energies of the plants; therefore, as soon as the pseudo-bulbs show the least sign of shrivelling, cut off the spikes. After passing out of flower the plants should be placed near the roof glass in a house having an intermediate temperature. *D. formosum* quantum should receive similar treatment after passing out of flower. Evergreen *Dendrobiums*, such as *D. thyrsiflorum*, *D. densiflorum*, and *D. chrysotoxum* should be placed in the intermediate house after completing their season's growth, and afforded only sufficient water at the roots to keep the leaves fresh and the pseudo-bulbs plump.

LYCASTE.—Plants of *L. Skinneri*, *L. Ballinae*, and *L. Mary Gairdri* will soon be finishing their growth and sending up flowers from the bases of the new pseudo-bulbs. The roots should be kept somewhat drier but on no account should they be allowed to shrivel for want of moisture; the check they will receive from having less water at the roots will cause a larger quantity of flowers to push up at one time than would otherwise develop. These plants grow well in a light position in the Odontoglossum house provided the temperature does not fall below 50°. *L. leucantha*, *L. aromatica*, *L. Doopeii*, and *L. cruenta* require water less frequently; these Orchids are best grown permanently in the intermediate house.

THE FLOWER GARDEN.

By W. J. GUNSE, Gardener to Mrs. DEMPSTER, Keele Hall, Staffordshire.

EARLY-FLOWERING CHRYSANTHEMUMS.—There is no advantage in leaving border Chrysanthemums in the open after this date. After lifting those required for stock purposes in these gardens last autumn, several dozen plants were left in the beds, but not one survived the winter. Before lifting see that the labels are tied securely to each variety. Plant them closely together in shallow frames to obtain stocky growth suitable for cuttings. Where there is a shortage of frames the stools may be planted in boxes and wintered in a cold house near the roof-glass. Albeit air

on all favourable occasions, only employing just sufficient fire-heat to exclude frost.

WICHURAIANA ROSES.—All the *Wichuriana* hybrids are suitable for furnishing pergolas, trunks of trees, trellises, and walls. As the plants will occupy the same position for several years, let the ground be well drained and thoroughly worked. If the soil is poor remove it to a depth of 3 feet and 3 feet in width, replacing it with a mixture of old turf, decayed manure, leaf-mould, and bone meal. For covering trellises, pergolas, or trunks of trees choose such varieties as *Excelsa*, *Dorothy Perkins*, *Alberic Barbier*, *Mrs. F. W. Flight*, *Blush Rambler*, *Gardenia*, *Hiawatha*, *White Dorothy*, *Flower of Fairfield*, and *American Pillar*. Weeping standards of some of these varieties are very effective when planted in the background of mixed borders.

LILY-OF-THE-VALLEY.—Beds of *Lily-of-the-Valley* become crowded after a few years, and unless the crowns are replanted they become weak and fail to flower. Trench the ground and mix with it a liberal amount of decayed manure, leaf-mould, and, if the soil is of a heavy, retentive nature, a quantity of old potting soil or sand. Lift the crowns carefully and select the finest for pot culture or for planting in special beds. Plant the crowns in rows made 12 inches asunder, and allow a space of 6 inches between the crowns. Small crowns planted in reserve beds will make good plants, suitable for putting into permanent quarters next year. Give the beds that were planted last year a light top-dressing of decayed manure and leaf-mould, after all weeds and rubbish have been removed.

FALLEN LEAVES.—The difficulty of obtaining farmyard manure in any quantity is increasing. As Keels are now being used, and these are incorporated with the manure available, including decaying vegetable matter and burnt ashes from the rubbish-yard. The labour difficulty has delayed the work of sweeping paths and drives, excepting those in immediate use. Now most of the deciduous trees have shed their leaves these will be collected and placed in convenient positions for future use. Large quantities will soon be required for forcing early vegetables.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to Lady NORTHCOLE, Eastwell Park, Kent.

BULBS FOR EARLY FLOWERING.—Examine bulbs of early-flowering Tulips and Narcissus, which were potted up early, and plunged in leaf-soil or fibre, at intervals, to see what progress has been made. Remove all those that have started into growth freely and filled their pots with roots. Place them in a frame and shade the frame with a mat for a few days until the foliage has become green, when they may be exposed to the light and air. A batch should be taken into the forcing house every week or ten days, according to requirements. Tulips will respond to hard forcing better than most bulbs. Daffodils should not be subjected to a high temperature or some will fail to bloom, and others grow weakly and not last well. Bulbs of this class, when in full growth, require plenty of water, and liquid manure or soot water to aid the development of the blooms.

CYCLAMEN LATIFOLIUM.—Early plants of the Chinese *Cyclamen* are developing their blooms, and should be encouraged to grow freely. Arrange the plants thinly, on a damp bottom if possible, in a light house. The day temperature should range between 55° and 60°, admitting a little air and increasing the ventilation as the temperature rises with sun-heat above 60°. Give the plants a little weak manure water, or top-dress them with a little very fine soil in which a small quantity of concentrated fertiliser has been mixed. Though the flowers of *Cyclamen* are not always satisfactory for use as cut blooms, small flowering plants are suitable for placing in china vases and similar receptacles in dwelling-rooms, as the blooms remain fresh for a long time, few other plants giving better results. The late batch of plants intended for flowering in spring may be grown 10° cooler; these late plants will give blooms of large size and substance.

EDITORIAL NOTICE.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHERS; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 41.6.

ACTUAL TEMPERATURE.—Office, 41, Wellington Street, Covent Garden, London, Thursday, November 22, 10 a.m.: Bar, 29.9; temp, 54.5°. Weather—Cloudy.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Balls at 67 and 68, Cheapside, at 3 o'clock, by Protheroe & Morris.

New Zealand Cushion Plants.

To those familiar with the curious cushion plants, such as the various New Zealand *Raoulia*s, Mr. Foweraker's description* of the mat plants and cushion plants of the Cass River Bed, Canterbury, S. Island, New Zealand, will be of great interest.

The district in which occur the plants described by Mr. Foweraker consists of the lower portion of the Cass Valley—a flood-plain about 4½ miles long by nearly two miles in breadth, with the river occupying a small strip in the centre. The river flows as a network of runlets, in the dry season narrow and isolated, but in flood meeting and forming a considerable stream. Cushion and mat plants are met with over the whole river plain, but are most numerous and interesting in the river bed itself.

The bed consists of water-worn rock in masses which range from lumps several feet in thickness to mere particles of sand. The characteristics of such a soil and situation are poverty of nutritive salts, a stony substratum rapidly drying out, and plenty of underground water; desert conditions above ground, but a plentiful supply of moisture for the roots of plants. Thus in spite of a high rainfall and the water supply below, the conditions are those of a desert, and the vegetation reflects those conditions in its xerophytic character.

On the "transition terraces" which lie between the river bed and the edges of the flood plain *Raoulia tenuicaulis* is the dominant plant, and one of the first to become established. It spreads as a greenish or greyish mat a yard or more in diameter; ultimately neighbouring mats run together and form patches covering areas of 30 square yards and more. This species also hangs over the edges of the terraces bordering the stream and helps to consolidate the bank, giving protection from weathering and river erosion.

* "The Mat Plants, Cushion Plants, and Allied Forms of the Cass River Bed (Eastern Botanical District), New Zealand," by E. Foweraker, *Trans. New Zealand Institute*, Vol. XLIX, June, 1917.

By its position it is very liable to be covered with sand during inundations, but its rapid growth enables it to "grow out" of this sort of danger. As is to be expected from its situation, *R. tenuicaulis* is less of a xerophyte than the other species occurring in more waterless parts of the valley.

Another plant which joins this species in invading and helping to reclaim the newly exposed shingle is *Raoulia australis*. Like the former species, it is a mat plant, and possesses, though to a less degree than *R. tenuicaulis*, the power of rapid growth. On the upper terraces *R. lutescens*, of slower growth, is found on the open shingle, and often forms cushions curving over the edges of old watercourses. Its cushions are more or less circular, raised in the centre, of smooth contour, and its surface is the smoothest of all *Raoulia*s. During summer its colour is glaucous, owing to the greyish tomentum of the leaves, but in winter it is grey, tinged with pink. The leaves are small, coriaceous, densely hairy, and contain water-storing tissue—all xerophytic characters which assist in enabling the plant to grow in situations devoid of humus.

The cushion plant best known to botanists in this country is *Raoulia Haastii*. It occurs on the upper terraces—its slowness of growth confining it to those situations.

The cushions formed by *R. Haastii* are large—more than a yard across and 5 inches deep. They are bright green in summer and chocolate-brown in winter. The periphery and surface of the cushion are irregular, the surface being thrown into numerous mounds and hollows formed by the young plant growing over or round obstacles which it encounters. Though irregular in contour, the surface is smooth owing to the compactness and uniformity of the branchlets.

On the oldest terraces occurs *R. subsericea* in the form of large, flat mats, so loose as to allow other plants to grow up within the space it occupies.

R. glabra is ubiquitous in the Cass Valley, and grows as a lax mat. *R. Menziesii* also forms an irregular mat on the old terraces.

A true cushion plant of this region is *Scleranthus biflorus* var. Other plants with mat or cushion habit found in the river terraces are *Coprosma Petriei*, as a wide-spreading mat, *Pimelea prostrata* var. *repens*, *Muehlenbeckia axillaris*, and *Acaena micropphylla*. It is interesting to observe that, as the names given above indicate, the cushion or mat habit of growth has imposed itself on members of diverse families: Polygonaceae, Caryophyllaceae, Rosaceae, Thymelaeaceae, Rubiaceae, and Compositae, and in this fact is an interesting example of what is often referred to as convergent evolution—dissimilar organisms taking on similar forms.

The most striking peculiarity of such forms is the occurrence of "filling materials," that is, structures—matted branchlets, for example—which provide for the

compactness of the cushion or mat, collect sand, and in which often run a greater or smaller number of adventitious roots. The filling material, composed of humus from dead leaflets, blown sand and debris, forms a medium of considerable water absorbing and water holding capacity, converts the cushion into a sponge, and renders the plant to some extent independent of its substratum. Thus the large cushions of *Raoulia Haastii* are quite moist inside even though all round them the shingle is quite dry.

That the form is well adapted to its environment is evident from the manner in which it withstands wind, rain, frost, desiccation, and snow, to all of which tests the mat and cushion plants are put. It is noteworthy that the long tap root so characteristic in desert plants is conspicuous only in *Scleranthus* and *Pimelea*. It occurs in other of the cushion and mat plants, but an adventitious root system developing early checks the growth of the main tap root. The genus *Raoulia* exhibits an interesting series of forms, progressing toward and achieving the perfect cushion. Thus *R. glabra* is large-leaved, lax, with large rosettes; *R. subsericea* is similar, but denser; *R. australis*, which lives on the shingle, is more matted; *R. lutescens*, a true cushion plant; *R. Haastii*, one in which the cushion habit is yet more pronounced; *R. eximia*, of dry Alpine and sub-Alpine rocks, and the famous vegetable sheep of New Zealand, a subject of curiosity to all observant visitors at Wisley and other rock gardens.

NATIONAL CARNATION AND PICOTEÉ SOCIETY (SOUTHERN SECTION).—The Southern Section of the National Carnation and Picotee Society will hold an exhibition on Tuesday, July 16, 1918, at the Drill Hall, Buckingham Gate, Westminster, in connection with the fortnightly meeting of the Royal Horticultural Society.

GARDENING BY SOLDIERS.—The land cultivated by soldiers around the various military camps has been inspected by officers of the Food Production Department. They report that the Commanding Officers not only express themselves satisfied with the results of Potato spraying, but have asked for lectures to be given during the winter to the men engaged in cultivation.

COMMERCIAL ALCOHOL.—Preliminary tests having proved satisfactory, the Food Production Department has arranged for an extensive experiment in the making of commercial alcohol from damaged or undersized Potatoes at a distillery in Scotland.

INSTRUCTION IN HORTICULTURE.—With the object of increasing the production of food and securing its preservation, arrangements have been made by the Food Production Department for systematic courses of instruction to allotment societies and similar bodies during the winter. The courses of instruction will include: (1) Lectures by a staff of twenty experts selected by the Royal Horticultural Society; (2) lectures on Potato disease and the results of this year's spraying, by members of the staff of the Food Production Department; (3) demonstrations in drying and other methods of preserving fruit and vegetables.

DEFERMENT OF POTATOS.—Our French correspondent A. M. sends us the following note on this subject: "The hundred-year-old collection of Potatoes maintained at Verrières-le-

Buisson by MM. VILMORIN-ANDRIEUX ET CIE. is interesting from the point of view of degeneration. The collection was entrusted by the French Agricultural Society in 1815 to the great-grandfather of the late PHILIPPE DE VILMORIN. Three plants of each of 120 varieties are propagated each year. The progeny of these varieties have been described from time to time in successive editions of the 'Catalogue Methodique et Synonymique des Pommes de Terre.' Many of the varieties have had only a brief duration at Verrières, and the collection is only maintained by replacing each year those that disappear. Of the 120 varieties originally planted only about one dozen survive, and these

November 14, referred to the inferior seeds which had in the past been sent into this country from abroad, containing frequently admixtures of old seed, and pointed out the protection which would be given to farmers by the new institute. The President called attention to the fact that the station must be considered as a war emergency measure, and expressed his appreciation of the help which had been received from Professor BURGER and Mr. STAPLETON, and from the seed dealers and merchants of this country, who in spite of the serious depletion of their staffs, and difficulties under which they were working, had given their best efforts ungrudgingly to help in the establishment of the

at £1,100, so that the necessity for economy had been fully met, and he hoped that the testing station would develop eventually so as to become an Institute of Applied Botany.

WAR ITEMS.—Four dishes of Apples, each dish containing six fruits, were sold by auction for the benefit of the Red Cross funds at the Exchange News Room at Liverpool on the 14th inst. The fruit was given by Messrs. KINGS, LTD., Bassett Street, and the sum realised was £119, or nearly 10s. per apple.

—Gunner C. W. CONNELL died on the 10th inst. in No. 3 Canadian Casualty Clearing Station. He enlisted in the R.G.A. in January,

FIG. 80.—BRASSICA CAULIFLORA, LADY MANNINGHAM BUTTER. Colour of flower yellow. (See R.H.S. Awards, p. 235.)

only as a result of the special care given to them. Of those that "carry on" three are relatively vigorous, and are varieties still grown in France. They are La Chave (Shaw), La Marjolain, and La Vilette, but it is to be noted that these plants grow to-day even if they are not from the original stocks."

"GARDEN MONTHLY."—The *Newspaper World* announces that the *Garden Monthly*, published for some years by the Educational Company of Ireland in Dublin, has suspended publication "until the dawn of a brighter day."

OPENING OF NEW SEED TESTING STATION.—The President of the Board of Agriculture and Fisheries, on opening the new Seed-Testing Station at 70, Victoria Street, Westminster, on

November 14, referred to the fact that England had an institute 16 years ago (in Scotland 4 years ago), and that the one now inaugurated would work in cooperation with the Irish and Scottish institutes. In future the farmers, instead of purchasing seeds with foreign certificates, would have seeds with the certificate of this institute, and this would give them a measure of assurance of quality which they had not hitherto been able to obtain. The President mentioned, with great appreciation, the services rendered by Mr. WEAVER in establishing the institute, and also referred to the appointment of Mr. STAPLETON, one of the leading authorities on seeds in this country, as director. The institute had been established at a cost of only £500, with an annual expenditure estimated

at £1,100, so that the necessity for economy had been fully met, and he hoped that the testing station would develop eventually so as to become an Institute of Applied Botany.

WAR ITEMS.—Four dishes of Apples, each dish containing six fruits, were sold by auction for the benefit of the Red Cross funds at the Exchange News Room at Liverpool on the 14th inst. The fruit was given by Messrs. KINGS, LTD., Bassett Street, and the sum realised was £119, or nearly 10s. per apple.

—Gunner C. W. CONNELL died on the 10th inst. in No. 3 Canadian Casualty Clearing Station. He enlisted in the R.G.A. in January,

1911, and was sent with his company to St. Helena, returning before Christmas, and he has since served in France. Gunner CONNELL was apprenticed in the gardens of Colonel W. H. Wrayton, Skelton Castle, Skelton-in-Cleveland, and he was afterwards employed in the gardens of the Earl of Eglarshere, Worsley Hall, Manchester. At the time of his enlisting in the Army he was employed in the Orchid department at Scampston Hall Gardens, Rillington.

PUBLICATIONS RECEIVED.—*The Life of the Rt. Hon. Sir Charles W. Dilke, Bart., M.P.*, By Stephen Gwynn, M.P., and Gertrude M. Tuckwell. 2 vols. (London: John Murray.) Price 36s. net.—*Agriculture and the Land*. By G. F. Bosworth. (Cambridge: The University Press.)

SOOTY BLOTCH ON APPLES.

The extraordinary prevalence of sooty blotch (*Asphylium Pannii*) has been noticed incidentally in my previous notes. The varieties most extensively attacked in my orchards were Cox's Orange Pippin, Charles Ross, Bramley's Seedling (see fig. 31), and Blenheim Pippin. This disease is widely prevalent in the United States, but has not excited much attention in this country. Marce, in his *Diseases of Cultivated Plants and Trees*, does not mention it. Damp weather and lack of sun-dried air are predisposing causes of the attack and development of the fungus. *Southern Grower*.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

AUTUMN CROCUSES.—I read with interest, as I always do, Sir Herbert Maxwell's "Notes from a Galloway Garden," in the issue for November 10. He expresses surprise at the little use that is made of autumn-flowering crocuses. Extraordinary use of them is made by rats and mice, which doubtless accounts for their scarcity, whilst *Colchicum* are never touched by them, though growing in my garden side by side. I know of no plant, root, or bulb which is more often attacked by rats and mice,

Aitchisonii is even finer. In our Scotch climate the Autumn and Winter-flowering Crocuses almost call for, and certainly deserve, the comforts of a cold frame. *Formakin*.

RAISING VARIETIES OF NEW FLOWERS FROM SEED.—One sentence in the note on "Rose-American Pillar and its Origin," by Mr. Eastlea, p. 196, was particularly interesting to me. It was that in which the writer stated that Mr. McGredy had raised several Gold Medal Roses from one seedling plant. This bears out my experience in the case of another quite different class of plants, namely, the Fuchsia. With this I had, at least, a fair measure of success, some of my raising being now well-established varieties. At first the results were indifferent, till, talking one day with Mr. Lodman, an old-time gardener, and a well-known raiser of Fuchsias, he pointed out (what I had already experienced) that many good kinds would produce very few, if any, fertile seeds, and even of that limited number none of the progeny ever approached the parent in quality. He instanced a case of his own, in which the breeder planted a seedling of no particular class, yielded a crop of good seeds, and the plants raised from it gave a great variety of quite superior flowers. I then set to work as far as possible on the same lines, and, though a slow process to carry out, good results ensued. My best seed-bearer was one with a pinkish-white corolla, and it yielded varieties with white, pinkish, and dark corollas. The flowers

SOCIETIES.

ROYAL HORTICULTURAL

NOVEMBER 20.—The fortnightly meeting, held in the Drill Hall, Buckingham Gate, Westminster, on Tuesday last, was accompanied by an exhibition of moderate extent. In normal times Chrysanthemums and other autumn flowers are extensively shown at the November meetings, with winter-flowering Begonias, Primulas, Ferns, and Carnations. These were represented on Tuesday, but by smaller and fewer exhibits. The largest individual display was in the floral section, and consisted of a table of winter-flowering Begonias, reminiscent of the groups which used to emanate from Messrs. Veitch's nurseries in the days when these Begonias were more or less novelties. The Floral Committee recommended Awards of Merit to two new Chrysanthemums and to the Duchess of Bedford's fine strain of *Primula obconica* known as Eureka.

Besides several fine groups, many interesting novelties were submitted for award to the Orchid Committee, and general admiration was aroused by the beautiful yellow *Draso-Laelio-Cattleya* Lady Manningham Butler (see fig. 80), which well merited the First-class Certificate and Silver-gilt Lindley Medal received. The other awards included two Awards of Merit and one Cultural Commemation.

The Fruit and Vegetable Committee found for inspection only a few seedling Apples, but none was considered worthy of award.

The lecture on the cooking of fruit, which was to have been delivered by Mr. Hermann Senn, was postponed.

Floral Committee.

Present: Messrs. H. B. May (chairman), G. Routhie, J. W. Blakey, C. R. Fielder, J. Jennings, J. Heal, T. Stevenson, C. Dixon, H. J. Jones, J. Dickson, C. E. Pearson, E. H. Jenkins, G. Paul, W. G. Baker, S. Morris, E. A. Bowles, R. C. Notcutt, R. Hooper Pearson, A. G. Jackman, H. Cowley, W. J. Bean, W. A. Bilbey, and J. F. McLeod.

AWARDS OF MERIT.

Chrysanthemum Brilliant.—A medium-sized Japanese variety, of deep crimson colour, with golden reverse. The florets are rather short and somewhat stiff, but the tone is exceedingly rich. Shown by Messrs. H. J. JONES, LTD.

Chrysanthemum Princess Mary.—A clear yellow sport from Queen Mary, of which it is a replica in all respects save colour; a Japanese exhibition variety of the largest type. Shown by Mr. CHARLES PAGE, Dropmore Gardens, Maidenhead.

Primula obconica "Eureka" (strain). This plant received an Award of Merit at the meeting on May 8, 1917, but the award was made on the present occasion for the strain. In the large batch exhibited on Tuesday the colour ranged from rose pink to deep carmine; some of the blooms have a very pretty crimson ring round the clear yellow throat. Shown by ADELINE DUCHESS OF BEDFORD, Woodside, Chertsey, Richmond (for Mr. J. Grooms).

Groups.

The following awards were made to collections—

Silver Flora Medal to Misses TANNER and TAYLOR for winter-flowering Begonias; their best varieties were Emily Clibran, Octina, and Clibran's Pink. They also showed a new variety named Mrs. Harry Barton, which has an upright habit, and produces semi-double, lemon-yellow blooms, some of the petals of which have a very faint suffusion of pink. The flowers are about 1½ inch across.

Silver Rankian Medals to Messrs. H. B. MAY AND SONS, Upper Edmonton, for Ferns, Begonias, and *Primula obconica*; Misses PETER AND FRYE, Ilorsted Keynes, for Perennial-flowering Carnations, including their novelties *Maria* (a large bloom of light pink colour), *Malva* (a corolla-scarlet), and *Gravel* (pink purple).

Bronze Flora Medal to Messrs. PETERS, Baywater, for decorative shrubs and berried plants in pots.

Bronze Rankian Medals to Messrs. ALWOOD BROS., Wivelsfield, for Perennial-flowering Carnations; ADELINE DUCHESS OF BEDFORD, for

FIG. 31.—BRAMLEY'S SEEDLING APPLES AFFECTED WITH SOOTY BLOTCH.

and they have destroyed the straggling shoots with me times without number. How they can discover the bulbs of, say, *Crocus speciosus*, be it dormant, in leaf, or in flower, beats the wit of man to know. These bulbs have long been favourites of mine, but it is exasperating to find, on one's return after a few days' absence, the clumps destroyed or the grass matted with holes. Rats, I think, are the worst offenders (they can eat more), but there is a field-mouse or vole, somewhat flat and red, which I think rejoices in the name of *Arvicola agrestis*, which is most destructive. Now for the remedies, which, alas! are scarcely able to cope with the destroyers. I find traps baited with the ordinary dainties of cheese, oatmeal, and other foods offer no attraction whatever to the vermin, but, baits of nuts (Brazil nuts are possibly the best), are irresistible. I encouraged owls, and introduced not a few, but, unfortunately, they ate my ringdoves, which had given me much pleasure, cooing among the branches in the garden. I think the most effective plan I have yet found for protecting the bulbs is by placing a piece of netting with very small mesh, say, not more than ¼ inch, over the bulbs when they are planted, or even on the surface of the ground where the bulbs are, and when this is covered with some carpeting plant, such as *Veronica repens* or *Artemisia biacoloris*, it is never seen, and helps to keep the *Crocus* bulbs cleaner in dirty weather. *Crocus speciosus* is one of the best, but *C. speciosus*

were fertilised with different coloured kinds. In raising varieties with light tube and sepals, I never met with much success. H. T.

PLANTING RHODODENDRONS (see p. 199).—In the case of Rhododendrons, better results are obtained from mid-April planting than autumn planting in average seasons. Both temperature and moisture are favourable, and the sun has not attained sufficient power to cause a severe strain upon the resources of the plants. The necessity of excluding lime from soils and composts to be occupied by Rhododendrons is recognised, and peat with sand is commonly employed with success, but a good, light garden soil containing plenty of humus and no rank manure suits many of the stronger varieties quite as well as the more elaborate preparations. One of the strongest points in my mode of procedure is to transplant quickly. *James A. Power, Aldenham*.

THE LATE MR. MARSHALL.—My father had charge of Mr. William Marshall's collections of plants the whole time he had them, and I have by me all the certificates and prize cards won by these collections, which number nearly 400. They include 10 Gold and 4 Silver Medals and 45 R.H.S. Certificates, which will show to what extent Mr. Marshall cultivated Orchids. The Lindley Medal, although awarded, for some reason was not handed either to Mr. Marshall or my father. My father was elected a member of the Floral Committee of the R.H.S. in 1872. *H. Wilson, East Drive Gardens, Bonchurch, I. of W.*

Primulas; Messrs. STUART LOW AND Co., Bush Hill Park, for Perpetual-flowering Carnations; Messrs. W. WELLS AND Co., Merstham, for Chrysanthemums, a very pleasing exhibit, in which only two varieties were used, Bronze Beauty (single) and Lady Stanley (pink decorative variety); and Mr. G. REYNE, Keston, for Nerines and hardy plants.

Orchid Committee.

President: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Vetch, Messrs. Jas. O'Brien (hon. secretary), J. E. Shill, W. Bolton, Fred. J. Hanbury, C. J. Lucas, J. Charlesworth, C. H. Curtis, Patricia Ralli, A. McBean, T. Armstrong, R. A. Rolfe, F. K. Sander and Walter Cobb.

AWARDS.

FIRST-CLASS CERTIFICATE.

Brasso-Laelio-Cattleya Lady Munningham Butler (B.C. *Duglyana-Mossia Queen Alexandra* × *L.C. Uphi*), from Messrs. ARMSTRONG AND BROWN, Tunbridge Wells.—This flower is a triumph for the hybridiser, and one of the best yellow Orchids ever raised, bearing out our expressed remarks as to the potency of the somewhat despised *Laelia xanthina*, which, with *Cattleya Dowiana aurea*, produced *L.C. Uphi*, as a satisfactory element in producing yellow hybrids. The large, perfectly formed flower (see fig. 80) is buttercup yellow, the disc of the imely crumpled and fringed lip being of the darker tint. The substance of the flower is good, and the habit of the plant free. A Lindley Medal was also awarded for the plant.

AWARDS OF MERIT.

Sophro-Laelio-Cattleya Anzoc, var. *Festinus* (S. *L.C. Marathon* × *L.C. Dominiana*), from Messrs. CHARLESWORTH AND Co., Haywards Heath.—A finely-shaped flower of a clear rosy mauve colour with a reddish tint over the sepals and petals and light claret-red front to the lip. *Odontoglossum General Allenby* (*crispum nigrescens* × hybrid), from Messrs. FLOXY AND BLACK, Slough. A handsome seedling, having claret red sepals and petals with small, white bases and narrow, white margin; the broad, white lip has a large claret blotch in front of the yellow crest.

CULTURAL COMMENTARIES.

To Mr. J. E. SMILL, Orchard grower to Baron BURSO N. MOORE, The Dell, Englefield Green, for a superb plant of the white *Cattleya Astron*, with ten flowers on a spike, and similar to that for which a First class Certificate was awarded at the last meeting.

GROUPS.

The Duke of MAREBOROUGH, Blenheim Orchard grower, Mr. J. Smith, exhibited the new *Cattleya* President Wilson Blenheim variety (*labiata alba* × *Fabia* Blenheim variety), a charming flower with sulphur-yellow sepals and petals, the lip having a vein of magenta rose in front; and *C. Vepris*, with rather small flowers, but richly coloured lip.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Surrey (gr. Mr. Collier), showed *Brasso-Laelio-Cattleya Antoinette* (C. *Portia coerulea* × B. *L. Helon*), with a good spike of flowers very closely resembling a good *C. Portia* and with the colouring of the ordinary form of that hybrid, but not showing conclusively the B. *Duglyana* or *L. tenebrosa* in B. *L. Helon*, although there was an appreciable indication of fringing in the margin of the lip.

MESSRS. ARMSTRONG AND BROWN were awarded a Silver Flora Medal for a group of good hybrid *Cattleyas* and *Laelio-Cattleyas*; the best plants were the new *Laelio-Cattleya Alma* (L. C. *Ernesti* × C. *Dowiana*), a pretty yellow flower; *Cattleya Maggie Raphael* (also brilliant flower); and the white-petalled C. *labiata* Mrs. E. Ashworth.

MESSRS. CHARLESWORTH AND Co. were awarded a Silver Flora Medal for a bright group composed mainly of fine specimens of the orange-coloured *Epidendrum vitellinum autumnale*, with white xanthoxes varieties of *Odontoglossums*, *Odontioida Hypatia* (*Odm ardentissimum* × *Oda. Diana*) is a pretty novelty with claret sepals and petals and lilac-coloured lip with claret blotch in the centre.

MESSRS. J. AND A. McBEAN, Cooksbridge, staged a selection of good hybrids, including *Cat-*

tleya Bellona, *Brasso-Cattleya Penelope*, *Sophro-Cattleya Pearl*, and showy scarlet *Odontiodas*. Messrs. FLOXY AND BLACK showed *Sophro-Laelio-Cattleya Eros* and a finely-spotted hybrid *Odontoglossum*.

Fruit and Vegetable Committee.

President: Messrs. W. Poupard (in the chair), W. Wilks, W. Bates, W. H. Divers, E. Beckett, A. Bullock, A. H. Allan, Edw. Harris, F. Jordan, E. A. Bunyard, F. R. Ridley, and Owen Thomas.

A new Lettuce was exhibited by Mrs. M. DOWELL MATTHEW, Little Heath Wood, Potters Bar, Herts (gr. Mr. W. H. Newton), named *Winter Beauty*. Its chief point is its decorative quality. The heads are very small, the outer leaves are a delicate green, slightly mottled, and the centre is golden, with a faint apricot flush, almost amounting to rose colour. The Committee requested that the variety should be sent to the Wisley Gardens for trial.

NATIONAL CHRYSANTHEMUM.

NOVEMBER 19.—At a meeting of the Floral Committee of the National Chrysanthemum Society, held at Essex Hall, Strand, on November 19, only three new varieties were shown, and one of these, named *Quinola*, a deep yellow Pompon of good type, the Committee decided to see again grown in natural style. It is of American origin and was imported in 1915, and grown and shown by Mr. H. Hussey, Matford Lodge, Exeter. The question of the size of exhibition Pompon blooms was again considered.

The Executive Committee met at Carr's Restaurant in the evening, when Mr. Thos. Bevan presided. It appeared that after all accounts are paid the Society will close the year with a small balance in hand. Arrangements for carrying into effect the proposed testimonial to Mr. Richard Witty, the retiring secretary, were left in the hands of Mr. John Green, Mr. T. Bevan, Mr. E. F. Hawes and Mr. C. H. Curtis.

way at Edgubston. For several years Mr. Parton was a member of the Committee of the National Carnation and Picotee Society, but his energies were directed principally to the success of the Midland Society, of which body he occupied at various times such important positions as secretary, vice-chairman, treasurer, and on the death of Mr. Robert Sydenham in 1915 he was appointed chairman. Mr. Parton grew *Aurucias* successfully, and for several years his exhibits were a feature at the Midland Show of the National Primula and Aurucida Society. Soon after the outbreak of war he joined the Sportsman's Battalion, and later was transferred to another regiment. He went to Egypt, and at the time of his death held the rank of sergeant. In business Mr. Parton was a builders' merchant and brickmaker at King's Heath, where he was held in high esteem. He was 43 years of age, and leaves a widow and three children, the eldest of whom is serving in the Army.

W. A. THOMSON.—We regret to record the death, on November 14, of ex-Baillie William Anson Thomson, Penicuik, for many years treasurer of the local horticultural society.

R. W. CLUCAS.—The *Florists' Exchange* records the death, on October 6, at Sparkhill, New York State, of Mr. R. W. Clucas, proprietor of the Palisades Nurseries in that town. Mr. Clucas was born in Liverpool in 1860, and while still a youth entered the seed business, first in his native town, and later with Messrs. Daniels Bros., of Norwich. He emigrated to the States in 1878, and was employed for about ten years with Messrs. Peter Henderson and Co., and a further ten with Messrs. Pitcher and Manda. Later he entered business on his own account, and created a flourishing establishment at Sparkhill. He leaves a widow, one young son, and four daughters.

CROPS AND STOCK ON THE HOME FARM.

RENOVATING ORCHARDS.

It is a rare occurrence to find a well-managed orchard on a farm. So much is this the case that when a tree is blown down it is often allowed to lie for years instead of being cleared away and replaced by another and better variety. Some orchards contain little in the way of variety, and the sorts are mostly of use for cider only. This need not be so, as many others make excellent cider, none better than Bramley's Seedling, and not even the first quality fruits of this are required. The fallen fruits can be advantageously utilised for this purpose, which is surely more profitable than selling them at 1s. per bushel. I would strongly urge farmers who have orchards to do all that is possible to make them remunerative. If the land is already devoted to trees that bear only half crops, it would be better to fully crop such land with improved varieties of Apples. Bramley's Seedling, Newton Wonder, Lane's Prince Albert, and King Edward VII. are all excellent late kitchen sorts. Grandier and Norfolk Beauty ripen in September and October. Of dessert varieties, Beauty of Bath (August), Worcester Pearmain (September), Blenheim Pippin (October), and Cox's Orange Pippin, in use in November, all succeed as standards.

In filling up gaps with these I would suggest that they should not be planted exactly on the same sites as previous trees occupied, but a little on one side, so that the soil may be fresher. When planting, trench the site fully a yard deep if the soil is heavy, and plant on the surface, mounding up the roots with a prepared compost of roadside refuse, wood ashes, and decayed manure. Add manure freely to the soil 6 inches under the roots to induce vigorous growth, so that a large head will be quickly secured, remembering that the larger the area the branches cover in a short time the better the return of fruit. Some writers say add no manure at planting time; my advice is to do so, to incite vigorous growth.

Another important item in the renovation of existing trees is that of pruning. Where trees have been neglected, and the branches have grown too thickly together, shutting out light and air from the inner parts of the trees, success is

Obituary.

MR. W. H. PARTON.—We regret to record the death, from syncope, of Mr. W. H. Parton, late of Moseley, Birmingham, which occurred in Egypt on the 29th ult. Mr. Parton was a well-known amateur Carnation grower and exhibitor, whose presence will be much missed at such shows as Birmingham, London, and Southampton. It was in the year 1899 that Mr. Parton made his first appearance as an exhibitor in his native city of Birmingham, where he won a 1st Prize for six dissimilar Carnations. In 1905 he was well to the fore, winning the Champion Silver Medal at Birmingham, offered to the most successful exhibitor in the amateur classes, a success he repeated in the following year.—Mr. Parton always looked back with pleasure to the year 1905, when he won the Silver Cup for the greatest number of points in the third division at the National Carnation Society's Show in London, as well as the Silver Medal offered in the Second Division at Southampton; whilst at Birmingham he had sixty-two prizes to his credit, and these latter secured for him the premier award of a silver medal with a total aggregate of 254 points in the open classes. He also won the Silver Medal for single blooms in very strongly contested classes, and in the following year succeeded in again winning the two last named medals with blooms of superior merit. At the Southampton Show in 1911 he secured the much-coveted Sir George Cooper Silver Cup with nine 1st Prizes and four 2nd Prizes out of thirteen entries. In the following year he won the last named Cup outright with twelve 1st Prizes and two 2nd Prizes out of fourteen entries. Mr. Parton, who won upwards of 300 1st Prizes for Carnations, favoured the showing of flowers as grown with their own foliage, and for five years out of six he won 1st Prizes for twelve triplicates shown in this

not possible until the conditions are altered. Commence by cutting away weakly branches that cross stronger branches, for a drastic thinning will induce more vigour in the remaining branches; the trees will then produce stronger shoots and improved foliage.

If the trees show signs of a want of vigour, and the variety is worthy of added labour, remove the turf 10 feet from the stem all round; and under the top slip of soil fork in half decayed farmyard manure freely.

Another method is to dress the grass with basic slag, for 50 feet around a large tree at the rate of 10 cwt. per acre during November, and in March give sulphate of ammonia at the rate of 1 cwt. per acre. When basic slag is sown on the surface of grass cattle should not graze there for at least six weeks.

PREPARING THE LAND FOR ONIONS.

It cannot be said that the Onion crop of this year has been an unqualified success. One of the chief causes of failure was a want of preparation of the soil. Then, the dry weather during April and May had a deterrent effect upon the growth, leaving the plants at a standstill for some time. Moreover, the frequent showers in August were in favour of the spread of mildew.

Onions like a deep rooting medium in stiff soil, but resent stagnation at the roots. Extra deep ploughing should be done early in the autumn, to ensure good drainage and a satisfactory surface tilth.

Small plots should be trenched, but larger areas can be ploughed.

The Onion is a voracious feeder on manurial stimulants. When ploughing or trenching the land, add farmyard manure liberally. If this is scarce, basic slag can be substituted at the rate of 6 cwt. per acre, sown evenly over the surface when ploughing in the autumn. A second and shallower ploughing in February will be an advantage.

THE 1918 POTATO CROP.

WHERE Potatoes were grown on newly ploughed up grass land this year, the same site should be better suited to receive the same crop next year. The turf will so have mixed with the soil as to make the ploughing and future cultivation much easier. After burning the haulm and any diseased tubers left on the land, plough at once at least 6 inches deep, leaving the surface as rough as possible, to be turned into a good tilth by the action of the weather.

The method known as "sprouting" or "boxing" the seed for next season's planting has a beneficial influence on the future growth of the haulm, and even those who grow Potatoes on a large scale should adopt this method. When the sets are prepared in this way, there are no gaps in the rows, an earlier start into growth is made, and the haulm is stronger in consequence. A convenient size for the boxes is the following:—Length, 2 feet 6 inches; width, 14 inches; depth, 2 inches. The corner pieces should be 2 inches square and 5 inches high, to allow of one box standing on another, to economise space. The stout corner pieces are used also for the nailing of the sides and ends, which should be of light, half inch match-boarding.

The setting up of the tubers affords employment for wet days. They should be kept in a light, airy shed, free from frost. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham, Hants.*

THE CORN AND HAY CROPS.

The total production of Wheat in England and Wales in 1917 is estimated at 7,164,639 quarters, or 350,000 quarters more than last year; and the yield per acre, 29.88 bushels, is 1½ bushel below the average of the ten years, 1907-16. Although the yield per acre of Barley is three-fourths of a bushel smaller than in 1916, the total production, 5,539,513 quarters is 560,000 quarters greater, owing to the increased area under this crop. The total production of Oats, 10,956,765 quarters, is 450,000 quarters more than in 1916, and the largest crop since 1907. This large crop is due to the increased area, as the yield per acre is 1½ bushel less than a year ago, and about the same amount below average. Beans are a very poor crop, and are the smallest crop recorded since 1855, both in total production and yield per acre.

Peas are rather more satisfactory, and the total production is slightly greater than last year, but still much below normal.

The total production of hay from Clover and rotation grasses is 2,405,468 tons, or nearly 500,000 tons less than the large crop of last year. The yield per acre, 23.60 cwt., is 4½ cwt. lighter than in 1916, and nearly 1 cwt. below average. The total production of hay from permanent grass, 5,149,557 tons, is also less than in 1916, by some 300,000 tons; the yield per acre in this case being rather over 3 cwt., less than last year, and 1½ cwt. under average. Taking all kinds of hay together, the total production is 7,550,000 tons, which is 1,230,000 tons less than last year, but nearly 1,000,000 tons more than the total productions of 1915.

ANSWERS TO CORRESPONDENTS.

CABBAGE ROOTS DISEASED: *Lanark.* The roots of your Cabbages and Wallflowers are attacked by Clubroot, or Finger-and-the-disease. The application of gas-lime to the soil would certainly check the spread of the disease, but if you use the lime in this form the ground must not be planted for some months afterwards. Bad drainage, and a consequent damp condition of the ground, is often a contributory cause of the disease.

FRUITS OF COMMON LAUREL: *Bansha.* We have never heard of the fruits of this shrub (*Prunus laurocerasus*) being used as food. The following is from *Lindley's Vegetable Kingdom*, p. 556: "The leaves, bark, and fruit of the common Laurel, and the oil obtained from them, are virulent poisons." In view of this we should advise you to leave them severely alone, in spite of their sweet and agreeable taste.

GRAPE SHEEVING: *B. Collins.* That the berries of Black Alicante turn black may be the result of the vines bearing an excessive crop, or because the roots, if in outside borders, are too wet, and consequently too cold. If the softening of the berries continues it will be advisable to cut the bunches and to place the shoots in bottles of water containing a few small pieces of charcoal. When the bunches are required for use take them out of the bottles and place their ends in water at almost boiling point; this will sometimes help to plump up the berries again. It is not advisable at this stage to attempt to swell the berries by watering the border. The same remarks apply to the varieties Prince of Wales and Gros Maroc. The last-named should be used first, as it is not a good keeping Grape, even when well ripened. When all the Grapes are cut and the vines pruned, it will be advisable to examine the border, and see that the drainage is perfect. If drain pipes are employed they should be placed just below the bottom of the border; they should be allowed a good fall, and be provided with an outlet.

NAME OF FRUITS:—In the naming of fruits, we desire to oblige our correspondents as far as we can, but the task would become too costly and too time-consuming were there no restrictions. Correspondents should observe the rule that not more than six varieties be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. The fruits should be just approaching ripeness, and they should be properly numbered, and carefully packed in stout boxes; cardboard is often smashed in the post. A leaf or shoot of each variety is helpful, and in the case of Plants, Branches and Straws, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. By neglecting these precautions, correspondents add greatly to our labour and run the risk of increased delay and incorrect determination. We do not undertake to send answers through the post, or to return fruits. Fruits and flowering plants must not be sent by the same box. Delay in any case is unavoidable.

A. P. M. 1. White Nonpareil; 2. Twenty Ounce; 3. Claygate Pearmain; 4. Small's Admirable—*W. M. Cellini—Epsom.* 1. Decayed Pear; 2. Vicar of Winkfield; 3. The Queen; 4. PRUNING OF APPLE TREE: *G. Yorke.* Certain varieties of Apple usually produce their flower-buds on the ends of the shoots, and, fearing to injure the crop, the cultivator is apt to leave them unpruned, with the result that long, straggling growths are made that have to be supported with props. This has happened in your case, and if you find it necessary to keep the branches shorter your plan should be to prune back a few each year. Those you prune will not bear fruit in the following season, but one or two new shoots selected to grow from the cut branch should bear in the following year. With care you could manage in this way, but, all the same, these tip-shoot fruiterers give some difficulty when planted in sites which provide but little space for shoot extension.

LIBRARIER: *E. M. M.* The value of one acre of established Rhubarb in pre-war days was between £30 and £45 per acre, and the yearly value would range from £15 to £30 or more, according to the state of the market. In present times Rhubarb may be considered a more valuable crop, notwithstanding the difficulty in obtaining sugar. The past season has been probably one of the best that Rhubarb growers have experienced for many years, and much higher prices than those quoted have been realised.

The Modern Pied Piper

"LIVERPOOL" VIRUS

EXTERMINATES
RATS & MICE

Rats and Mice come out of their holes, not to dance to the pipes of the charmer, but to die—a less poetic but far better way of exterminating these pests.

Apart from the desirability of getting rid of the vermin on the grounds of health, think of the tremendous wastage of food due to their raiding of our granaries, cornfields and gardens. It is a patriotic duty to destroy them.

In tins ready prepared with bait: for Rats 2/6 and 6/-; for Mice 1/8 and 4/- tins.

Full particulars from
EVANS SONS LESCHER & WEBB, Ltd.,
66, Hanover Street, Liverpool.

SUBSTITUTE FOR RUSSIA MATS.
"FRIGI DOMO" CANVAS.
Made from prepared Hair and Wool.

A good non-conductor,
2 yds., 3 yds., and 4 yds. wide,

and pattern from—

THE GARDENERS' CHRONICLE occupies a position in the world of horticulture which is absolutely unique. Founded in 1841, in the very dawn of scientific botany, it has advanced, step by step, with the gradual development of horticulture in its country. Its founders were men of high distinction, Sir Joseph Paxton, the greatest gardener of his day, Dr. Lindley, the world-famous botanist, the late Sir C. W. Dike, the Baronet, with his typical English love of gardens, these were among the little group of men who launched the "Gardeners' Chronicle" on a long and progressive voyage. The paper had a fine and progressive tradition to maintain, and has preserved from the first a progressive spirit. It was, long ago, the confidence of its readers, and that confidence it still enjoys.

PRIVATE.

GLAMORGAN COUNTY COUNCIL.

HORTICULTURAL DEMONSTRATOR AND ADVISER

The Glamorgan County Council invites APPLICATIONS for the APPOINTMENT of a HORTICULTURAL DEMONSTRATOR AND ADVISER for assisting the Occupiers of Cottage Gardens, Allotments, and Small Holdings in such areas as will from year to year be selected within the Administrative County of Glamorgan.

Candidates must have acted as apprentices to Gardeners, and have held situations in which they were in charge of and responsible as Foremen or Head Gardeners for Flowers, Fruit, Vegetables, and Hot-house work.

Experience as Foremen in vegetable or market gardens is an essential qualification.

Preference will be given to applicants who possess an Examination Certificate of the Royal Horticultural Society.

Applicants must provide and be able to ride a bicycle. Salary 50s. per week, with an allowance at the rate of 2s. per annum in addition for the upkeep of a bicycle.

The appointment will be for one year, subject to one month's notice on either side, and will be renewable annually.

The person appointed will be required to give his whole time to the service of the County and to reside where from time to time directed.

Applications, stating previous experience and age, with copies of three recent testimonials, must be received by the Chief Education Officer, Glamorgan County Hall, Cardiff, on or before 10 AM, on Saturday, the 15th day of December, 1917.

Candidates, whether personal or written, will be a qualification of any candidate. T. MAXWELL FRANKLIN, Clerk of the County Council, Glamorgan County Hall, Cardiff, 24th November, 1917.

WANTED, in Nobleman's establishment in Kent HEAD GARDENER, where 6 to 8 are usually kept; small amount of Glass; cottage in garden; permanent position if suitable. Full particulars a.s. to experience, &c. to E. B. 130, Mount Street, Berkeley Square, London, W. 1.

WANTED, HEAD GARDENER (WORKING), must be experienced in the growing of Fruit and Vegetables under Glass and Outside, as well as in the packing and marketing of same; preference will be given to a married man, steady over military age, with small or no family, and whose only training had been in gentlemen's private gardens. There is a large staff of garden workers, and only competent men, who can be well recommended, need apply. Good wages given.—Apply, giving particulars and references, to THE ESTATE STEWARD, Dolkeith House, Reading Road, Henley-on-Thames.

WANTED, good HEAD WORKING GARDENER, for one man, and help given.—Apply, Mrs. CURSON, Leathersheep Hall, Melton Mowbray.

WANTED, GARDENER (HEAD WORKING), where five are kept, single, malleable; fully must have had good experience inside and outside good wages. Apply, stating experience, to W. L. SMITH, Frost's Court, Newbury.

WANTED, good all-round SINGLE-HANDED GARDENER for Farnham, Bants; malleable; willing take charge pony and fowls; wife care; can help in house when wanted. State age, wages with references, and references, to F. W. BELKE, Murray Lodge, Newmarket.

WANTED, SINGLE-HANDED GARDENER, must be well up all round and willing to look after a pony. State full particulars and wages required (with references) to R. S. WYBE, Wildwood Lodge, North End, Hampton, N.W. 3.

WANTED, good all-round SINGLE-HANDED GARDENER for Somerset, must be in-credible with wife, D. A., Box 5, 41, Wellington Street, Covent Garden, W.C. 2.

WANTED, GARDENER, good Single-handed, experienced inside and out. State age, wages, and references.—BRADLEY, Union Club, Southport.

ON INCREASED FOOD PRODUCTION.

PREPARING THE GROUND FOR NEXT SEASON.

IN most gardens there is now a considerable amount of space uncropped, and it should be decided at once when and what steps shall be taken towards preparing the ground for next season. Soils vary much, and no hard-and-fast rules as to their treatment can well be laid down, so much depending upon circumstances. Some land is best left alone until near the time of cropping, but other types ought to be dug at once; in some cases bastard trenching would be beneficial, whilst in others ordinary trenching would be better treatment. When to manure and what manures to use are questions that require consideration, whilst soils may be greatly improved by the addition of a variety of other materials, soluble and insoluble.

Heavy soils under good cultivation usually prove the most fertile. They consist largely of clay. When first taken in hand, it is best not to attempt trenching of any kind, but the drainage ought to be made perfect. As early in the winter as possible the ground should be dug with a fork to its full depth, and strawy manure from the stable, only partially decayed, freely buried in the trenches. This kind of manure is slow in decomposition, and acts mechanically in dividing naturally close soils. Frosts, winds, sunshine, and rains will further break down or pulverise the roughly laid-up spits, and if a spring dressing of fine sandy soil, leaf-mould, wood ashes, peat, mortar rubbish, or burnt clay is forked in, the improvement effected in a comparatively short space of time will be of a permanent character.

Caustic lime applied at the rate of one ton to a quarter of an acre of ground is an excellent dressing, either for heavy soils newly broken up or for any that have been freely manured of late years, and where decomposition is slow. Place it in four bushel heaps and cover it with soil until it is slaked, then spread it over the surface of ground that has been dug some few weeks in advance, and fork it into the soil. Never bury lime deeply, it will find its way down quickly enough. The other substances, whether in mixture or separately, should also be well mixed with pulverised soil, and not deeply buried. After the top spit has been improved, and exhausted of some of its fertility, the time will have arrived for double digging.

There are some soils that contain so great a

percentage of clay that it is scarcely possible to alter their character quickly. In some cases it is unwise even to dig them many weeks in advance of cropping, some clays when pulverised assuming the consistency of birdlime. The majority of heavy soils, however, should be roughly dug as early as possible in the autumn or winter, and if soon pulverised pay well for being forked over, without disturbing the manure underneath, in February or early in March; for often the surface is finely divided when cropped, but underneath are great hard, cold lumps, which often remain in that state through the summer. The second turning discovers and brings these to the surface to be pulverised.

On no account interfere with retentive soils in wet weather, or the surface will be made pasty before it is turned in, and be years in recovering its original fairly open state. Nor should cow manure be used if supplies can be obtained from the horse stables. The former material makes the land heavier and colder than before its application, and is suitable only for light land, whereas strawy manure, as already stated, acts differently. All wheeling on heavy land must be done as much as possible either when the surface soil is frozen or in a dry state, planks for wheeling on being necessary at all other times.

Medium soils vary much, but there is generally a good depth of free working, yet fairly retentive soil, which is improved by deep cultivation from the outset. Soil that contains 20 per cent. or more of clay, of a sandy or gravelly nature, should not be brought too hastily to the surface. First prepare it by bastard trenching, and the admixture of decaying substances, such as vegetable refuse and solid manure of any kind, and then a reversal of the spits, if clay is not very abundant, may safely be attempted.

Mixed farmyard manure is the best manure for these medium soils, and they will stand plenty of it. Manure in a half decayed state may be dug in now, and the surface of the ground laid up to be improved, sweetened, and broken down by frosts. A dressing of lime is usually required about once in seven years. No garden where vegetables are grown can flourish indefinitely without it. The soil becomes sour and plants will not thrive.

Light soils of a very free-working character have their disadvantages as well as the rest. In particular, sandy soils are not sufficiently retentive of moisture. If the subsoil is not of a very chalky or gravelly nature, much may be done towards improving the physical properties of a light soil by first bastard, and then really trenching it. Clay sometimes underlies these sandy soils, and the bringing of about three inches of this, or even less, to the surface, and well mixing with it, would completely change its character for the better. It is to the absence of clay that the poorness of sandy soils is to be attributed. If either clay or marl can be obtained, it would pay well to spread about twenty loads of this over a quarter of an acre of ground, doing it either in autumn or early in winter. It must be left exposed to all weathers until broken down to a finely divided state, when it should be forked into and mixed with the surface soil, but not buried deeply. This admixture of clay or marl has the effect of at once making the ground more retentive of moisture. If no clay can be obtained, it is not advisable either to manure or dig long before the ground is wanted for cropping purposes. Should manure be buried in the ground much before the roots of plants are there to absorb the food thus placed within easy reach, the chances are much of it will be washed down the drains and washed. Better build the manure into a square heap (it ought to be well decomposed for light soils), place a layer of fresh soil underneath and another on the top, thereby preserving its best properties and increasing the bulk against the time it is wanted.

Roughly digging or ridging light soils in the

autumn or early winter is a mistake, for the reason that they are already too finely divided. Failing a dressing of clay or marl, collect a great heap of road trimmings, decayed garden refuse, and cow manure. A heavy spring dressing of this mixture, or one given when the ground is being dug, will serve to improve its depth, retentiveness, and productiveness.

Bastard trenching consists of breaking up the soil two or more spits deep without changing the position of the different layers, thereby increasing the depth and fertility without running any risks of bringing the poor, unworkable subsoil to the surface in injurious quantities. Some few soils, principally those of an alluvial or deposited character, may safely be trenched outright, but by for the greater proportion would be little short of ruined for years if other than bastard trenched at the outset.

Having a breadth of clear ground, the present is a good time to trench, it being of importance that the mass should settle again prior to being cropped. The nature of the subsoil must determine whether ordinary or bastard trenching shall be carried out. Poor subsoil must not be brought to the surface, nor rich soil buried deeply. Work in plenty of good manure. Trench any hard or weedy ground. The deep moving facilitates the passage of air and water through the soil, and an opportunity is afforded of burying troublesome weeds, except such as Bindweed and Couch Grass, which ought to be picked out as trenching proceeds. Heavy ground that has been previously bastard trenched two or three times will most probably have the subsoil sufficiently well prepared for bringing to the surface. It must be borne in mind that a spit of fresh, clayey subsoil when first brought to the surface may run together badly, and render working and cropping difficult for several years.

Full trenching is done by first digging a trench 20 inches wide and two good spits deep, the whole of the soil being wheeled back to where the work is to be finished. Mark out the next 20 inch width, and from this dig and throw the top spit into the bottom of the trench in front; on the top of this deposit the bottom spit of the second trench, leaving it in as rough a state as possible, thus exposing it to frosts. Repeat the operations until the last trench is reached, which will be filled in with the soil wheeled from the front.

In this manner the positions of the two layers of soil will be reversed, this operation greatly increasing the depth and productiveness of the whole mass. When ground is being trenched for any crop requiring a rich, deep root run (no vegetable crop that I know is influenced more by deep trenching than the large Onions that are so common nowadays), plenty of solid manure or decaying vegetable matter may well be mixed with each spit, but for ordinary crops no manure ought to be needed. *James I. Poise.*

POTATO SIR JOHN LLEWELYN.

I HAVE been very interested in the various articles on Potatoes in the columns of the *Gardeners' Chronicle* during the last few weeks, but, so far, I have not seen any mention of the variety Sir John Llewelyn. Your correspondent J. F. mentions a few good varieties; I wonder if he has tried this one, and what was his experience with it? It is a heavy cropper, has first-rate quality, and is an excellent keeper. Mr. Wm. Taylor asks for varieties which may be taken off the ground by the end of July. I presume he does not mean that they must be ripe for storing? Sir John is ripe here by the end of August. Last year, as we shall all have cause to remember, was a bad year for disease. I never found one tuber affected in this variety; later sorts were all more or less bad, so I had them used first, and reserved the Llewelyns till late spring; in fact, we were using them to the end of June, and what surprised me most, the quality was as good as ever to the last, a point readers will agree with me is a very im-

portant matter. Complaints were frequent about Potatoes being black late in the spring; for a change I heard nothing but compliments regarding these tubers. All Potatoes were stored in the same conditions, in a disused stable, and from time to time turned over and the sprouts rubbed off. Although Sir J. Llewelyn is an early variety, it gave the least trouble in this respect, and probably that had a lot to do with its eating qualities. I planted more of it than any other variety, and have had a fine crop; the soil is a light loam. *T. N. D., Willinghurst Gardens, Guildford.*

EARLY AND MID-SEASON POTATOS.

In reply to Mr. Taylor (see p. 191), I would recommend The Norseman, a kidney variety,

moved and a light dressing of sulphate of ammonia was scattered between the Bean rows and lightly tamped in. The crop of Beans was pulled up in September and hung up in an open shed until thoroughly dry, then the pods were picked off and put into a sack, and threshed out by beating the sack with a stick. The yield from this crop was 27½ pints. The quality of this Bean when cooked as a Haricot is excellent.

A sowing was also made of Sutton's Forcing; half a pint of seed was sown between the Celery trenches, the yield from which was 16 pints. This Bean is a dwarf grower and matures early; the seeds are smaller than the Brown Dutch, nevertheless it may be recommended as a most suitable variety for

From 1 pint of Early Blue Peas sown in March I obtained 13 pints of dried Peas as food for winter use. These Peas were not sown so early as usual, and when drying off they were badly winnowed by the sparrows and did not prove such a success as when sown in the autumn; consequently I have already sown 1½ pints of William I. and 3 pints of Early Blue, the crops of which will be used as dried Peas during the winter of 1918 and 1919.

There is one advantage in growing dried Peas—the land on which they have been grown is most suitable for a winter crop of Greens, and when the Pea seed is sown in the autumn the crop matures early. *G. H. W., Heath End Gardens, near Basingstoke.*

ONIONS ON THE SAME BORDER FOR TWENTY-THREE YEARS.

IN view of the fact that many vegetables at present are being grown on the same soil for more than one year in succession I may mention a case in my early experience. One border in a garden of 11 acres was set apart for the cultivation of Onions, and the gardener assured me they had been grown there for 20 years, to which I added three more while there. It was a fruit tree border, and the Apples, Pears and Cherries on the wall were very old, so that the border, probably, had not been trenched since they were planted. I was set to wheel a liberal quantity of well-rotted manure upon it, and then dig it spade-deep. This done, I was directed to give it a good dressing of well-rotted garden refuse. One year, I remember, the Onions were sown on March 12. When ready they were weeded and thinned. Soon after the Onion fly made its presence visible I watered the border once or twice with guano-water, and the Onions made rapid progress. Being intended only for home consumption we allowed only 3 to 4 inches between the plants. The crop was a heavy one, a large proportion weighing half a pound each, some more. This was before the days of Ailsa Craig and other big Onions. *J. F.*

THE THINNING OF CARROTS.

UNDER "Critical Remarks" (p. 201) Mr. C. Turner questions the necessity of thinning Carrots and Onions. He does not mention whether his Carrots were sown thickly or thinly, but to enable him to grip a handful of tops and draw up bunches of 5-8 specimens the former must have been the case.

My own experience differs from that of Mr. Turner. As a Carrot-grower of many years' practice I am convinced that, if the aim of the grower is to produce handsome roots, proper space must be allowed for development.

If Carrots are sown thinly none need be wasted, as it is quite possible, while avoiding any injury whatever to the permanent plants, so to withdraw the surplus ones that these latter may be used for cooking. Until this season I always allowed main crop Carrots to stand 6 inches to 8 inches apart in the rows; this enabled me to use the hoe freely and prevent the Carrot fly (*Psila rosae*) from ruining the crop.

Unfortunately lack of labour this season prevented the customary systematic thinning of crops, with the result that, instead of the usual, good-shaped Carrots, I have a double number of undersized, misshapen specimens. In regard to Mr. Turner's remarks on lifting, I may say that whilst I have known Carrots sown in August remain in the ground until spring and then yield a good supply of fresh roots, it is only a catch crop depending entirely on mild weather, favourable soil, and situations. The general practice is to lift and store main crop Carrots on the approach of severe weather (see Mr. Dunn's remarks, *Gard. Chron.*, Oct. 20, p. 158). This date is not unnecessarily soon; providing the crop is stored in sand in a cool shed, I find that the roots retain both firmness and flavour. *Arthur Scoble, Smalley Hall Gardens, Derbyshire.*

(Drawn by Mr. Francis Bangard.)

FIG. 82.—CURRANT FAX'S PROLIFIC (½ NAT. SIZE).

(See p. 217.)

and a heavy cropper. If planted early, lifted at the end of July, and carefully stored, the tubers keep sound until late in the winter. Windsor Castle is another variety that can safely be planted early and lifted early, and the tubers will keep well. *C. Davis, Holy Wells Park Gardens, Ipswich.*

HARICOT BEANS AND DRIED PEAS FOR FOOD DURING WINTER.

HAVING obtained at the beginning of the season one pint of Brown Dutch Beans from the R.H.S., three-quarters of a pint were sown in May between the rows of Spring Cabbage. At the end of June the Cabbage stumps were re-

use as a Haricot. On several occasions I have tried the Canadian Wonder, but as this variety is slow in maturing it is not suitable for our climate when grown for use as a Haricot.

The success with my dried Beans is partly due to partial failures in previous seasons, so I find one must choose suitable varieties, and the ground which they are to occupy must not be too rich, else they are apt to grow rank, consequently they mature late and cause endless trouble in drying.

I have other varieties which are not yet threshed out, but from the appearance of the crops Brown Dutch and Sutton's Forcing are my best.

A REVISION OF THE RED CURRANTS.

(Continued from page 206.)

THE VERSAILLES GROUP.

THIS group includes the descendants of the so-called *Ribes macrocarpa*, probably a large form of *R. vulgare*. The first variety known was the Cherry. They all possess very stout shoots that are easily broken off by wind or overcropping, large, thick and milky-green leaves, and buds that are apt to "go blind." Nearly all of the largest fruited sorts belong to this group, and it is very difficult in many cases to separate the different sorts, which often vary only in a few inconspicuous characters.

VERSAILLES (see fig. 65). Syns. Belle Versailles. La Versaillese, Eclipse, Magnum Bonum.

Flowers.—*Vulgare* type, eye slightly tinged red, petals wedge-shaped or linear, sepals turned back, rachis slightly downy.

Leaves.—Young state tinted brown, adult large, milky green, very stout, held nearly flat, leaf-stalk not channelled.

Fruit.—Bunch medium length, about 10 fruits, rachis a little hairy, keeping green when fruit is ripe, berries rather large, fairly dark, pedicels slender, rather long and lax, allowing fruit to hang loosely around the bunch.

Season.—Mid.

Buds.—Dark chestnut brown, standing well away, slightly hairy.

Growth.—Vigorous, rather upright.

Origin.—Raised by M. Bertin, of Versailles, about 1835, and put into commerce shortly afterwards. It was first named Belle de Versailles. A good and accurately coloured figure will be found in DeCandolle's *Jardin Fruities*.

CHERRY. Syn. Geise. I find it impossible to describe this variety. It is the first of its type, the *Macrocarpa*, and was sent from Italy about 1830 to M. Adrien Senebouse, of Bourg, Argenet, labelled *Ribes acrifolium*. Early authorities describe it as having fruit the size of a Cherry and only a few on a bunch. Of the varieties I have received as Cherry from modern sources, two only agree, the remaining five all present small differences, and no other variety illustrates better the extraordinary difficulty of deciding what is the original type. The distinctions are small, often only a difference in time of starting growth, a glabrous or downy rachis, the eye green or red, but as they preserve these unchanged over a series of years I cannot disregard them as negligible. None of them, however, corresponds to early figures and descriptions. In any case, the varieties grown under this name are so close to Versailles, and none is better in cropping, that it may, I think, be disregarded from the practical point of view in favour of that variety. It may be noted that for many years pomological authorities have been in disagreement as to whether there is any difference between the Cherry and Versailles, and I can only surmise that either the original Cherry has developed longer bunches or that it is now lost to cultivation.

FAY'S PROLIFIC (see fig. 82). Syn. Walkers.

Flowers.—Type, green faintly striped red, sepals just separated, petals wedged, eye red, rachis with downy hairs, and a few dark glands.

Leaves.—Large, milky green, very rugose, downward-pointing.

Fruit.—Bunches rather long, rachis with slight down, fruit large, hanging loose around bunch.

Season.—Early.

Buds.—Very long and pointed, on long supports, dark brown. Vascular bundles of leaf scar very prominent.

Growth.—Moderate, fairly open.

Origin.—Raised by Lincoln Fay in Chatauqua, New York, in 1863. Quite the best of its type, and most valuable for its earliness. The flowers show well before the leaves, and their peculiar yellow tinge as they open serves to distinguish this variety at that season.

ROUGE DE BORDEAUX. Syns. Grosse Rothe von Bordeaux. This is a poor form of the Versailles,

which it almost exactly resembles save in its poorer cropping qualities; of little merit.

Origin.—Undiscovered.

CACASIEHL.—**Flowers.**—Pale yellow, sepals apart, petals wedged, round, rachis almost hairless. Late flowering.

Leaves.—In young state dark red, adult indistinguishable from Versailles.

Fruit.—Bunch medium, rachis green, slightly hairy, berries medium.

Season.—Mid.

Winter buds rather short, round, pointed, well away, light brown, rather hairy.

Growth.—Strong, buds frequently abortive.

This has proved a poor cropper with me, and not worthy of cultivation.

which is the true type. My own efforts to procure a true stock have not been successful.

CHENONCAY. A distinct form of Versailles type, but with shorter bunches, and starting rather later than that variety. Of little merit.

WARBLER'S GRAPE. Closely resembling Chenoncay, but bunches very short at the end of a rather long stem. Has cropped very poorly with me, and is not worthy of retention.

BELLE DE ST. GILES. Syn. Schoene Von St. Gilles. Resembling Versailles very closely in nearly all characters, but the bunches are distinct, being moderately long and hanging around in a tight mass. It is, however, so apt to go "blind" that it cannot be recommended.

(Drawn by Mr. Francis Bangard.)

FIG. 65. RED CURRANT VERSAILLES (NAT. SIZE).

RED CROSS. Resembling Versailles, but having flowers with a green eye, leaves held more flatly than that variety, and starting later. A good cropper, but not so regular as Fay's Prolific. Raised by Jacob Moore, of Athens, New York, Cherry's White Grape.

NORTH STAR.—A green-flowered form of Versailles, the main difference being its very early habit of starting growth; but berries rather small. An accidental seedling introduced by the Jewell Nursery Co., of Lake City, Minnesota.

COVER (see *Card. Chron.*, August 1, 1896, fig. 26). This is considered by many to be identical with Fay's Prolific, but as I am told that when originally distributed it contained several distinct varieties, it is hopeless now to try and de-

PERFECTION (American).—A form of Versailles, differing in its habit of starting growth and flowering very early, but as it does not ripen so early as Fay's Prolific it has no advantage, and the fruits are also rather apt to run off. The variety Perfection of Laxton is quite distinct, and will be found under the Dutch section, said to be Fay's Prolific x White Grape. Introduced in 1912.

WINTER. This closely resembles Perfection (American), but it is earlier still in starting growth, and the fruit quickly attains its full size, but is long in colouring, so that it does not ripen before other early varieties. Subject to running off. A seedling of Versailles raised by E. Y. Teas, of Indiana. E. L. Bangard.

(To be continued.)

ORCHID NOTES AND CLEANINGS.

LAELIO-CATTLEYA GOLDEN WINGS.

A FINE flower of this pretty hybrid between *L. C. Ophir* (*L. xanthina* × *C. Downii aurea*) and *C. fulvescens* (Forbesii × *C. Downii aurea*) is sent by Mr. H. G. Alexander, Orchid grower to Lieut. Col. Sir Geo. L. Halford, K.C.V.O., Westorbirt, Telford. The flower, which is 6 inches across, has petals 2 inches wide and proportionately broad, and ovate sepals, both of a clear lemon-yellow colour. The lip, which is openly displayed and shows the fleshy white column, is yellow on the outside, veined and tinged with orange in the centre. The front is light rosy lilac, recurved at the apex, and showing indications of the *C. Forbesii* parent of *C. fulvescens*. Its clear yellow colour is another proof of the utility of *Laelia xanthina* in fixing the colour of yellow hybrids.

ODONTOGLOSSUM ETHELREDA.

This singular hybrid, remarkable for its very dark colour, was raised by Mr. De Barri Craw, send, Rosefield, Sevenoaks, between *O. Edwardii* and *O. triumphans*. The original plant, recorded in the *Gardeners' Chronicle*, August 3, 1912, p. 101, had a pink margin and tips to the segments. A much darker form is sent by Mr. H. Haddon, Orchid grower to Mrs. Bischoffsheim, The Warren House, Stanmore, taken from a seedling plant flowering for the first time there. The lanceolate sepals and petals are uniformly coloured dark mahogany brown, with a slight golden tint, and the front half of the narrow, apiculate lip, which is dark orange colour at the base, is coloured like the sepals and petals, but rather lighter in tint. In size and shape it is not what is usually expected of an *Odontoglossum*, but its very remarkable colour renders it acceptable.

CYRIPEDIUM JOHN HARTLEY

A FLOWER of massive proportions, resulting from a cross between *C. Reginald Young* (*Hitchinsiae* × *insigne* Herefield Hall) and *C. Shogun*, a good hybrid of unrecorded parentage but with strong evidence of *C. insigne* or *C. Dreadnought* in its composition. It is sent us by Mr. John Hartley, The Knowle, Morley, Yorkshire, the owner of this new hybrid, which secured a First-class Certificate and a Silver Medal at a recent meeting of the Manchester and North of England Orchid Society. It is one of the finest developments of the *C. insigne* type yet produced, showing plainly in its features the influence of *C. insigne* Herefield Hall, but enlarged and improved in every way. The lower two thirds of the dorsal sepal, which is 3½ inches wide, is pale yellowish green. The sides and upper part have a pure white margin, varying from half an inch to one inch in width, the central greenish portion of which has numerous dark chocolate-purple blotches and smaller purple spotting at the sides. The broad, flat petals and large lip are greenish yellow, tinged with rose.

PLANT NOTES.

SALVIA SPLENDENS.

SALVIA SPLENDENS has produced a ruddy purple sport in the Cambridge Botanic Garden. The flowers at once suggest those of *Salvia ianthina*, but the colour of that plant, which diffuses also in foliage, is blue-purple, while the purple of the novelty is distinctly ruddy. The flowers have a sombre appearance, but, nevertheless, may be regarded as having some beauty, and they are certainly attractive in contrast with everything else. The sport seems to have arisen from the base of a cutting that has not otherwise grown to any very great extent, but the cutting itself has the usual scarlet flowers, while the shoot from its base has grown

up far above it to a plant of perhaps 18 inches or more in height. I should be glad to know if the sport has already appeared in any garden? *R. Wynn Lynch.*

IRIS STYLOSA (UNGUICULARIS).

ON October 10 a flower of this lovely winter-flowering Iris was fully expanded. I have no record in these gardens of the plant being in bloom in October. The bulbs have only been planted about a year and a half, having been brought from my employer's other garden. The plants in flower are planted in front of a span-roofed vinery, among some rough sandstone, with prepared soil, and in a position fully exposed to the sun's rays. The charming flowers travel well, and open freely when picked in the bud state. *W. J. Cook, Abbot's Wood Gardens, Goddington, Surrey.*

TREES AND SHRUBS.

SOME CHOICE SPECIES OF BERBERIS.

IN recent years a great number of new Chinese trees and shrubs have received either first-class certificates or awards of merit from the Royal Horticultural Society. Among them are some striking species of Berberis, the most recent of which is *B. polyantha*, which was given a first-class certificate on October 25 last, and was illustrated in the *Gardeners' Chronicle*, November 3, p. 103. The profusion in which the clusters of bright coral-red berries are borne is therein well shown. This Berberis, which is very graceful in character, will attain a height of 6 to 10 feet. It is a deciduous species, and the young leaves and stems are tinged with red. The yellow flowers are borne in June and July. Discovered in 1899 by Mr. A. E. Pratt, this Berberis was first introduced by Mr. E. H. Wilson in 1901. It is in every way a most desirable shrub, and its first-class certificate is but the second awarded this year by the Floral Committee, the first being given to the now well-known *Robinia Kelseyi*.

Last year equal awards were made to two Berberis, namely, *Berberis subnuda* and *B. Sarcentiana*. The first-named, from the Wisley Gardens, is of doubtful origin, probably an accidental hybrid. Its rich, coral-red berries form a delightful autumn feature. It is deciduous.

The second, *B. Sarcentiana*, is evergreen, and is nearly related to the Himalayan *B. Hookeri*, but is said to be harder than that species. A native of Western Hupeh, China, *B. Sarcentiana* was introduced by Wilson in 1907. It is a bold-growing shrub, and has shoots freely furnished with light coloured spines. In the autumn some of the leaves become suffused with red and bronze, after the manner of the North American prunella-leaved species. The flowers are pale yellow, and the fruits black when ripe. Of the other Chinese Berberis, *B. Wilsonae* is still one of the best, while the larger growing *B. Stueppiana*, somewhat in the same way, is also a very beautiful. The compact growing evergreen *Berberis vernica* (buxa), whose dark, shining green leaves are glaucous on the undersides, is also a desirable shrub. *W. T.*

TURKEY OAK.

No deciduous tree stands exposure better on the west coast of Scotland than *Quercus cerris*, the Turkey Oak. It is seldom blown down, and is subject to no disease. This is remarkable, seeing that the species has its headquarters in the Mediterranean region. It may be worth while to record the dimensions of one blown down here in the gale of October 25. It carried an enormous head, which, being in full leaf, brought it to grief.—Height, 72 feet; clean bole, 13 feet; circumference at 4 feet high, 10 feet; at 12 feet, 9 feet. Messrs. Elwes and Henry report poorly of the timber of this species for outdoor use, but favourably for interior panelling and such work. It is very heavy, and is said to have a fine figure. *Herbert Maxwell, Monieith.*

THE KITCHEN GARDEN.

By J. DUNN, Foreman, Royal Gardens, Windsor

MUSHROOMS.—Horse-droppings should be collected daily, and placed in a dry, open shed, where they can be frequently turned, until sufficient have been got ready for making up a new bed. See that it does not become sour through want of turning, and that too large a quantity is not placed together. The temperature in houses from which mushrooms are being gathered should be kept as near 55° as possible. Do not apply fire-heat if the house can be kept warm enough without it. Syringe the walls and floor as it becomes necessary, and if the beds become too dry rain-water should be applied through a fine rose.

TOMATOS.—Young plants raised from seed in October should be kept close to the roof-glass. As soon as the small pots are well filled with roots the plants should be transferred into 5-inch pots, in a compost of turfy loam and leaf-soil, with a sprinkling of sifted lime rubble. Pot moderately firmly, and water sparingly until the roots reach the edge of the pots. Avoid cold draughts, and also high temperatures. Plants which are carrying a crop must not be allowed to suffer from want of water at the roots. Top-dress with turfy loam and decayed manure, and make the soil firm on the surface of the pots before water is applied. Do not allow the plants to become overworked. All side-shoots may be removed when quite small. A temperature of 60° will be suitable.

CARROTS IN PITS.—If brick pits are available a sowing of Early Horn Carrots may be made in December, in order to have a supply of young roots as early in the season as possible. The pit should be cleared out and a bed of new leaves made up to a depth of 4 feet, so that a mild and lasting heat may be produced. If the leaves have already been collected and allowed to ferment, they may be placed in the pit at once, and trodden tightly together until the surface is within 12 inches of the roof-glass. A bed of soil should then be placed in position to a depth of 9 inches. When this has been made level and moderately firm with a wooden rake the seeds should be sown, and covered with finely sifted soil to a depth of 1 inch. If the soil is in good order very little water will be necessary until germination takes place, but the surface may be lightly damped with a syringe on fine, sunny days.

LETTUCE IN PITS.—All pits in which Lettuce plants are growing should be ventilated as freely as possible without allowing rain to reach the plants. Remove decaying leaves, and stir the soil between the plants as often as possible with a small Dutch hoe. Examine the pit frequently, and if slugs are present sprinkle the edge of the bed with lime, and dust the plants with it lightly in the early morning. A sowing of some early-maturing variety may be made in boxes and placed in a slightly heated pit. When these young seedlings are large enough to handle they should be carefully pricked out in pits or boxes of fine rich soil, and a careful watch kept for slugs.

MUSTARD AND CRESS should be sown weekly, so that an unbroken supply may be maintained throughout the winter. A slightly heated pit or a Peach-house just started will suit the purpose well.

FRUITS UNDER IGLASS.

By Jas HUNSON, Head Gardener at Gunnersbury House, Acton, W.

YOUNG VINES.—It is somewhat early to prune young vines finally, but it is advisable to remove all the lateral growths. In a few weeks' time, when all the leaves have dropped, the work of pruning should be completed. These young rods should not be left unduly long, and the degree to which they are shortened should be governed, to a great extent, by the length of

rather, allowing three years for the rod to reach the top of a house of average dimensions. In houses of large size, four years should elapse before the young rods are allowed to reach the top of the rafter. Temporary vines, such as will be removed when the permanent vines require more space, may be allowed to grow longer in order that they may not interfere with the laterals of the others. On one occasion I left the rods of supererminent vines nearly their full length with good results. Certain varieties of Grapes break into growth very unevenly, and one of the worst in this respect is Lady Downie's Seedling. This trouble may be corrected to a large extent by bending the rod down to equalise the flow of sap. At the final pruning use scythe, or knoting, to dress the cuts against possible bleeding. These young vines must not suffer from drought at the roots, and for this reason a light mulch may be retained on the surface of the border. Young vines should not need an extension of the border the second year, but a little extension of the rooting area may be allowed to those in their third or fourth year.

OLDER OR PERMANENT VINES.—Well-established vines from which the Grapes have been cut may be pruned. Our vines are on the point of dropping their leaves, and there is no advantage in deferring their pruning after that stage. In my opinion, close spur pruning is best for all vines that are vigorous, with the exception of a few varieties such as Duke of Burgh and Prince of Wales, that do best on the long rod system. The spurs on old vines that are showing signs of exhaustion may be allowed to extend somewhat in order to secure a better choice of bunches. In doing this, however, the bunches will frequently be more straggling and loose. I would, however, not hesitate when dealing with rods upon which there may happen to be a few blanks in the spurs, to allow an upward extension to fill the gap. A good crop of fruit, rather than a good appearance, should be the primary object.

VINE EYE FOR PROPAGATION.—Whilst the pruning is being done some of the best ripened wood should be laid aside for purposes of increasing the stock. I prefer to propagate from eyes taken close to the spur, and always below the bunch; never, in my view, should the eye next the bunch be used, nor one beyond the bunch. When the prunings are being collected, select and tie in bunches some of the best ripened wood and plunge the shoots firmly in damp soil out of doors. Do not select for purposes of propagation shoots from vines that have been attacked by insect pests or mildew, or from old, weakened vines.

THE ORCHID HOUSE

By J. COLLIER, Gardener to Sir JEREMY COLMAN, Bart., Gatten Park, Beigate.

CATTLEYA, LÆLIA, AND LÆLIO CATTLEYA.—Autumn flowering Cattleyas, Lælias, and Lælio Cattleyas, such as C. Labiate, C. Bowringiana, C. Dowiana and its variety aurea, C. Hardyana, L. pumila and the many hybrids of these species, including C. Falcia, C. Manning, C. Porter, and L. C. Episcopa, are in bloom. The spikes should be cut directly the pseudo-bulbs show the least sign of shrivelling. After the plants have passed out of flower the sheaths should be removed, severing them as near as possible to the top of the pseudo-bulb, for if they are allowed to remain, moisture sometimes accumulates at their base and sets up decay in the leaves and new pseudo-bulbs. The plants at this stage should be afforded a period of rest in the coolest and best ventilated part of the Cattleya house. The roots should receive only sufficient water to keep the pseudo-bulbs plump, and the plants be given every encouragement to develop roots, but premature top growth must be discouraged. Plants of Cattleya Fiance that have completed their growth should be worked with extra care. They need only sufficient moisture to keep the root damp, but the supply may be increased slightly when the flower spikes are seen to be coming from the base of the sheaths. Cattleya Lawrenceana makes its growth during the winter months, and, in consequence, is a difficult plant

to cultivate. It should be grown in the warmest part of the Cattleya house, near the roof glass. The compost should be allowed to become quite dry between each watering; when moisture is necessary water should be poured only around the outer edges of the compost. From now onward through the winter, great care should be exercised in applying water to the roots of all Cattleyas and Lælias.

ODONTOGLOSSUM.—Plants of *Odontoglossum citrosum* that are nearing the completion of their season's growth should be suspended or staged near the roof glass in the cooler part of the intermediate house. The supply of water at the roots should be reduced gradually until after the new pseudo-bulbs are thoroughly developed; then moisture should be withheld for longer periods, affording only sufficient to prevent the pseudo-bulbs from shrivelling. This treatment should be continued through the winter and until the flower spikes are seen to be pushing from the centre of the young growths. Plants of *Odontoglossum grande* and *O. Schleperianum* that have passed out of flower should be placed on a dry shelf near the roof glass in a cool house, and rested. *O. Inseleyi* and its variety *Leopardinum* are producing their flower spikes, and should be liberally supplied with water until after the flowers fade, when they should be allowed a period of rest.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to Lady Northcott, Eastwell Park, Kent.

CINERARIA.—If not already done, plants of greenhouse Cinerarias should be removed from frames and placed in a light greenhouse, where they can be more readily protected from frost. Fire heat is only necessary to maintain the temperature at 50°. Plants of the earlier batches that are throwing up their flower spikes need a little stimulant, either liquid manure or a pinch of concentrated fertiliser, about once a week. The use of a little weak soot water will tend to keep the foliage healthy and green now the pots are well filled with roots, and the soil must never be allowed to become dry, or the foliage will quickly lose its freshness. A stage covered with gravel or crushed coke is much better to stand the plants on than open wooden stages, as the former provides a damp base. It is very noticeable how well Cinerarias thrive in a frame with an ash bottom, and late batches of plants may be kept in the frame for the present, if they are protected from frost. Fumigate on the first appearance of aphid, which is a troublesome pest of Cinerarias.

HERBACEOUS CALCIFOLARIAS.—Plants of herbaceous *Calcifolarias* thrive in cool, damp conditions, such as obtain in a cold frame. Young plants should not be allowed to become pot-bound in their earlier stages, but should be repotted as soon as they are well rooted. The size of the flowering pots should be regulated by the special requirements of each grower. If large plants are needed, the strongest specimens should be potted on, and finally grown in 3-inch pots. For general purposes 6-inch pots are the most suitable receptacles, but forcing must be commenced earlier in the case of small plants. Take measures to keep the plants free from green fly, which invariably causes the leaves to curl and the plant to become unhealthy. *Calcifolarias* that are badly infested with this pest rarely make good plants, even when they are fumigated.

FERNS.—All Ferns have completed their annual growth, and they will remain healthy in a lower temperature than hitherto. Many of these plants are forced into premature growth by keeping them in too much warmth during the winter, when they should be practically at rest. The roots should continue to be watered, for, as a general rule, Ferns should not be allowed to become dry, even in winter, though they do not require such large quantities of moisture as when in full growth. No manure should be given at this season. If slugs are troublesome, search for the pests at night with a lantern, and use *Lettuce or Cabbage leaves* as traps. The temperature at night should range between 40° and 45° allowing for a rise of 10° by day. Admit a little air on all favourable occasions.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to the Hon. ARTHUR J. DAVY, Abbots Wood, Godalming, Surrey.

MANURING FRUIT TREES. Farmyard dung should always form the staple manure for fruit trees; chemical fertilisers should be regarded and used as auxiliaries. Potash constitutes a large proportion of the latent ash of plants, and is a good fertiliser, whilst lime must also be present in the soil, and in greater quantity for stone fruits. Manure from a yard in which stock is fed is undoubtedly the best form of animal manure. In conjunction with this manure marlate of potash may be used with good effect at the rate of 6 lbs. to a pole, or 3 to 9 cwt. per acre. Phosphates should be given in the form of either bone-meal, basic slag, or superphosphate. In average soils of gardens very little manure is necessary for fruit trees until they commence to fruit. In the case of poor, light sandy soils, manuring at the time of planting is an advantage, and helps to give vigour to the growth. On rich land that has been well broken up, maiden trees are apt to become too vigorous, and may need lifting after a year or two to check excessive growth. It therefore follows that in manuring one must be guided by conditions and circumstances. Farmyard manure may be supplied as a top-dressing at any time with good effect, and especially on dry soils in high situations. Trees on high ground generally do better than those in low lying situations, and especially if the soil in the lower parts is inadequately drained.

GENERAL REMARKS.—Much useful work can be carried out during inclement weather, such as the cutting and sharpening of stakes, tying them in bundles, and crossing the points. Large labels may be made, painted, and the names written ready for use. Labels for Gooseberry and Strawberry plantations should be made 13 inches to 2 feet in length, and the name boldly written, to be observed at a distance. Work in dooms may also take the form of preparing cuttings of bush fruits. The cuttings should be made 10 inches to 12 inches in length, with all the lower buds pulled off, leaving about three or four only at the apex. The cuttings should be tied in bundles, named and numbered, and again plunged in soil to await a suitable opportunity for planting. Soils for various purposes should be mixed in an open shed. Shreds for tying can be cut into convenient lengths, and tools sharpened and oiled.

THE FLOWER GARDEN.

By W. J. GURR, Gardener to Mrs. DEMESTER, Keele Hall, Staffordshire.

HERBACEOUS BORDERS.—During mild weather, when the soil is in a friable condition, fork the borders over lightly and apply a top-dressing of short manure and leaf-mould in equal proportions. Certain plants will be benefited by placing a mixture of loam, leaf-mould and sand around them. Tender species may need protection from severe weather, and Bracken or leaves should be placed about them and kept in position with a few twigs. Advantage should be taken of fine weather to bring the work of planting to a close.

HELLEBORUS NIGER.—It is not advisable to remove Christmas Roses from the borders to frames, as this would check the plants severely and spoil the flowering next year. A better practice is to place spare frames or hand-lights over the plants *in situ*. The frames should be raised about 2 feet from the ground to permit the air to circulate freely. Remove all dead and decaying foliage, stir the soil lightly with a small hand-fork, and thoroughly soak the roots with manure water.

CUTTINGS IN FRAMES.—Cuttings of *Calcifolaria*, *Viola*, *Penstemon*, *Marguerite*, and similar plants are rooted, and the frames should be ventilated in mild weather. Strict attention in this respect will harden the plants and thus enable them to withstand severe weather much better than if they are coddled. Remove dead foliage and stir the soil lightly with the aid of a pointed stick. A good supply of Bracken or straw should be kept in a dry shed in readiness to cover the plants during very cold weather.

EDITORIAL NOTICE.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plans to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

SALE FOR THE ENSUING WEEK.

WEDNESDAY—

Bulls at 67 and 68, Cheapside, at 3 o'clock, by Protheroe & Morris.

*. *The sale of Japanese Dwarf Trees and Miniature Gardens will be held at Protheroe and Morris' Rooms on December 7, and not on December 17, as announced in the advertisement columns of the last issue.*

On Planting Roses.

Much has been written on the planting of Roses, and it will doubtless be admitted that the operation is one of the most important in the Rosarian's year. Yet the actual work is simple enough, the two essential points requiring care being merely to see that the plant is placed at the proper depth in the soil, neither too high nor too low, so that in the case of dwarfs the point of insertion of the bud is about one inch below the surface of the ground, and secondly, that the soil, after covering the roots, is carefully trodden down and consolidated.

The proper preparation of the bed is often a more important matter than the actual planting, and the amount of preparation required varies greatly with the character of the soil and the district. In naturally loamy or alluvial soils Roses will do well with comparatively little preparation, while in gravelly districts the greatest care and attention should be devoted to securing a rich and deep root run for the plants. Having given this caution, our present object is to treat of subsidiary matters well worth considering.

A certain amount of root pruning is usually desirable before planting, and when transplanting maiden plants care should be taken to cut off the stub of the stock beyond the insertion of the bud, and pare it close with a sharp knife. The object of this is to allow the plant to heal over the wound formed by cutting off the

stock; if the stump of the stock is left projecting it will decay back to the growing part, and may, and frequently does, introduce a fungous disease into the plant, which is often fatal. The purpose of root pruning is to reduce any long roots. In the case of plants purchased from nurseries, both these operations will probably have been performed before they leave the nursery, but it is well to see that the work has been properly done, correcting any deficiency, while with plants moved from one part of the garden to another root-pruning is generally necessary.

Moreover, the root of the plant should be examined to see that there are no suckers or upward growing roots likely to produce them, and if there are any suckers, to remove them with a sharp knife or secateurs close against the stem of the plant. This is particularly likely to be the case with standards that have been in the same place for some years.

It is often recommended that the hole for receiving the plant be made 2 feet square; this is scarcely necessary. It is, however, desirable that the hole be rather longer each way than the length of the planter's foot, for if not as large as this, it is difficult to press the soil down on the roots firmly and evenly all round.

It is to be remembered that the fine rootlets through which the Rose has been feeding itself have been torn up and destroyed in the act of removal, and that in the coming spring, before any great call is made upon the roots, numerous white roots will be formed, with which the plant will be supplied with water and salts through the summer.

It often happens that it is necessary without disturbing a whole bed of Roses to move out of it one or more of the plants that are not doing well, and replace them by young Rose trees, which are thus planted among the older plants, the roots of which are already in possession of the soil. Where this is the case, some extra attention to the new comer should be given, in order to ensure that it gets a good start. One of the best ways of effecting this is to scatter a few handfuls of bone meal in the bottom of the hole, and also in the soil that is being filled in over the roots; a method that is even better, and which may be combined with the last, is to bury a few good-sized pieces of turf under and around the roots of the newly planted tree. Somewhat similar considerations apply where a border has to be used which is not far removed from trees, and where their roots may be expected to invade it. Roses which have once become established will often do well in borders so near to forest trees that the roots of the latter may already have entered the border. In such cases as these, before the Roses are planted the border should be thoroughly trenched and enriched, and all invading roots cut away and pulled out. Fresh roots will in all probability invade later, but in the meantime the Roses will have become established, and it is quite possible they may not be greatly interfered with, provided

vigorous sorts are selected for planting, and there is no overshadowing of the plants by the branches of the trees. We do not suggest that a border liable to the invasion of tree roots should be selected as a site for Roses if there is an alternative. The ideal position for a Rose bush is in the open, where the plants can enjoy without competition the sun, air, and root-room; but some cultivators have not so much free space available that they can exercise an unfettered choice in the position of all the beds.

Considerable care is desirable in the choice of varieties for these tree-rooty borders, inasmuch as some succeed better than others. Curiously enough, many of the Tea section appear to do fairly well there; possibly the somewhat drier condition of the soil during winter is agreeable to them. Whatever be the reason, we have noticed that *Mme. Hoste*, the *Coquets*, pink and white, *Charles Dingee*, and *Auguste Comte* all do well, making good growth in borders that are not free from tree roots. The *Chinas*, also, will in many cases submit to these positions with tolerable grace, particularly *Comtesse du Cayla*, if given a certain amount of latitude at pruning time, as also will some of the *Polyantha Pompons*.

On the contrary, the *H.P.s* and most of the crimson *H.T.s* appear rather to resent such positions, whilst the only crimson Roses which we have seen moderately successful in such a position have been some pegged-down plants of *Avoca*. Varieties of orange tints, such as *Prince de Bulgarie*, *Edu Meyer*, and *Lady Pirrie*, have been uniformly unsuccessful in such positions, but have done well when removed to sunnier spots in the garden. Some pink *H.T.s*, such as *Mme. Léon Pain*, *Pharisier*, and *Mrs. E. G. Hill*, have succeeded perfectly.

It might be thought that in dry borders such as these, hard pruning, which diminishes the calls of the foliage upon the roots, might be beneficial, but the opposite seems to be actually the case, and so long as the plants can be prevented from becoming leggy and bare at the base, the more foliage they can be induced to carry the more successful they appear to be.

Regarding the best time for planting, no doubt it is best done from the end of October to December, and, if conditions admit, the earlier part of this period should be chosen in preference to the later. It is true that Roses can be planted, often with tolerable success, down to the end of March, but after Christmas there is a greater likelihood of partial failure. Unfortunately, the idea is still prevalent with many an amateur that he is doing rather a smart thing by delaying his order for the new plants he requires until spring, this, as he thinks, allowing the nurseryman to take the risk of winter. But he is entirely mistaken. Very few Roses die during winter. The trving time for Roses is the spring, particularly when very cold weather comes just as they have commenced growth. If, then, it should happen that the Rose has

only just been moved and its roots have no firm hold in the soil, it is much more likely to suffer injury, and even to be killed outright, by a cold spell of east winds, than an autumn-rooted plant over which the icy blasts may pass harmlessly. There is a great deal of truth in the old gardener's adage: "Plant in the spring, you may pray them to grow, but plant in the autumn, compel them to grow." *White Rose.*

A HYBRID CRAB (PYRUS FLORIBUNDA × P. NIEDZWEZKYANA).—In the early spring of 1911 a new hybrid *Pyrus* under the name of *Malus floribunda* var. *purpurea*, was purchased by the Kew authorities from M. BANNIER, of Orleans. The two small trees have since grown well and promise to become attractive specimen trees of

Westminster. It will be remembered that an announcement was published in these pages in July to the effect that the Government had commended the use of the Hotel Windsor, including the room leased to the Horticultural Club. In view of the fact that there are now but few hotels in the neighbourhood of Westminster still available for public use, and the knowledge that Horticultural Club members are not able to be in town as often as usual, it is felt that an arrangement to share the rooms of the Farmers' Club is the best that could be made. It is intended that the members of both clubs shall enjoy exactly the same privileges. Whitehall Court is situated immediately at the rear of the War Office, and has all the advantages of a first-class hotel.

ALLOTMENTS.—We have received from the National Union of Allotment Holders a copy of a resolution sent to allotment societies throughout the United Kingdom for signature, urging "the President of the

Board of Agriculture and the Director General of the Food Production Department to recognise the necessity of at once extending the tenancy of allotments held under the Cultivation of Lands Orders to such time as the said land shall be required either for immediate building or other urgent public purposes, and to take such steps as are necessary to provide that where tenants have to be dispossessed of their allotments from such causes other suitable ground shall be made available for their use. Further, that it is desirable that such legislation be at once introduced and passed so shall make it possible for allotments of a permanent character to be secured by all who are prepared to cultivate them."

THE TRANSPORT OF FERTILISERS.—Growers are strongly urged by the Food Production Department to place orders for superphosphate with their usual merchants at once. The railways will have great difficulty in providing sufficient trucks to secure rapid delivery in the spring, and it is essential that the traffic should be spread over as many months as possible. Makers have moderate stocks of superphosphate in hand at present.

FRUIT FARMING FOR DISABLED OFFICERS.—On behalf of officers disabled by war service the Ministry of Pensions is endeavouring to arrange with the University of Bristol for a special twelve months' course of training in fruit

FIG. 34 A HYBRID CRAB AND ITS PARENTS.
Pyrus floribunda. P. Niedzewkyana.

(Photograph by E. J. Wallis.)

The hybrid purpose.

moderate size. There is ample evidence of the influence of both parents in the hybrid tree, which is practically intermediate between the two, hence it is a distinct addition to the ornamental Crabs, attractive both in flower and fruit. In habit the tree is more upright in growth than *P. floribunda*, while the branching is light and graceful compared to the stiffer habit of *P. Niedzewkyana*. There is a slight shade of purple in the deep rosy-red flowers, but only sufficient to give them a distinct and pleasing shade of colour. When cut, the young wood, leaves and fruit all show evidence of *P. Niedzewkyana* as a parent, being permeated with the distinct purple-red colouring of that species. Quantities of the dark crimson red fruits were produced this season, the stalks not shape suggesting large cherries. We illustrate the two parents and the hybrid in fig. 34.

THE HORTICULTURAL CLUB.—We understand that negotiations are in progress for securing temporary headquarters for the Horticultural Club at the Farmers' Club, 2, Whitehall Court,

Board of Agriculture and the Director General of the Food Production Department to recognise the necessity of at once extending the tenancy of allotments held under the Cultivation of Lands Orders to such time as the said land shall be required either for immediate building or other urgent public purposes, and to take such steps as are necessary to provide that where tenants have to be dispossessed of their allotments from such causes other suitable ground shall be made available for their use. Further, that it is desirable that such legislation be at once introduced and passed so shall make it possible for allotments of a permanent character to be secured by all who are prepared to cultivate them."

TRADE WITH FRANCE.—The Board of Trade Journal states that H.M. Consul-General in Paris (Mr. W. R. HARRIS) reports that a firm in that city desires to get into touch with United Kingdom manufacturers of small tools, gardening implements, and lighting and heating apparatus, with a view to obtaining agencies for the

growing at a cost of about £100 for maintenance and £25 for University fees. It is expected that thereafter an officer will be able to obtain work for another year on an approved fruit farm, receiving practical instruction and maintenance in return for his services. When an officer's disability prevents him from returning to his former occupation, the Ministry can make liberal grants towards the cost of training. If a sufficient number of disabled officers come forward the Ministry hopes to open the course at Bristol early in 1918.

RAILWAY RATES FOR FRUIT AND OTHER GARDEN PRODUCE.—We have received from the Railway Clearing House, Seymour Street, London, N.W. 1, particulars of the new terms on which, at the end of the present year, perishable and other goods will be carried by passenger train or by other similar service. All consignors wishing their goods to be conveyed at reduced or "owner's risk" rates will be required to fill up, sign, and stamp a special agreement (to be obtained from the

address given above, or from the railway stations), or, failing this, to sign a separate Owner's Risk Consignment Note in respect of each consignment forwarded. Unless one of the alternative plans is adopted, consignments will be charged at the ordinary rate.

SALE OF "IMMUNE" POTATOS FOR EATING.

The Board of Agriculture and Fisheries have, by a general licence under the Seed Potatoes (Immune Varieties) Order, 1917, authorised the sale in England and Wales for consumption of Potatoes of the varieties King George V., Great Scot, Lochan, and Templar, which will not pass through a riddle having a 1½-inch mesh. The Food Production Department, however, points out that the provisions of any other Order of the Food Controller affecting such Potatoes must be complied with in the case of all sales permitted by this licence, and the licence must not be construed as an authority to deal with any Potatoes in contravention of the requirements of any Order relating to wart disease. At a later date the Board of Agriculture and Fisheries will be prepared to issue licences for the sale of these varieties for planting, but, for the present, such licences cannot be granted except in very unusual circumstances.

A STORY OF THE LATE MR. MARSHALL.—The late Mr. MARSHALL, as we stated in our memoir (see p. 202), though a man of strong convictions, was not apt to force his own ideas upon those charged with responsibility. Fifty years ago, when his Orchid collection was developing to its best, his gardener, Mr. WILSON, was allowed to practise his own methods of cultivation, and was very rarely interfered with by his keen but tolerant master. In the *Gardener's Chronicle* for 1871, pp. 253, 310, 300, 416, 515, 615, 712, 741, 775, 337, 374 and 937, there took place a somewhat heated argument in respect to the cool treatment of Orchids, the antagonists signing themselves respectively "G. H." and "Ex-Cantab." When all was over it turned out that "G. H." was really Mr. MARSHALL and "Ex-Cantab." his gardener, Mr. WILSON. No one was more surprised at this discovery than the immediate parties concerned, nor did anyone enjoy the joke so much as Mr. MARSHALL. The curious point about it is that whilst Mr. MARSHALL was advocating one kind of treatment his gardener was practising another kind and succeeding in a measure that left nothing to be desired.

RETIREMENT OF MONSIEUR LAFOSSE.—We learn from the *Revue Horticole* that Monsieur LAFOSSE, Director of the National Horticultural College at Versailles, is retiring from that position. He has been connected with the College from its foundation, and has won the esteem and affection of all with whom he has had to do—students, professors, friends, all retain for him the warmest sentiments. Although retiring from the arduous duties of the Directorship, Monsieur LAFOSSE will continue to conduct certain lectures.

A GARDENER'S FIFTY YEARS' SERVICE.—Mr CHARLES CRANSTON has completed his fiftieth year of service as gardener at Milton Lockhart, Lancashire. As mementos of the interesting occasion and in appreciation of his faithful service, Mr. CRANSTON has been presented by Mrs. LOCKHART with a watch bearing an inscription, and a cheque; and he has also received presents from other members of the LOCKHART family.

WAS IT? We regret to learn that Private JOHN HEWELL was killed in action in France on August 30, 1917. Deceased joined the Army in October, 1916, from Hackwood Park Gardens, where he was acting foreman. At one time he was gardener to the late Mr. ROBERT FITTOWAY, Shotsham Park, Norwich.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

LILIUM REGALE.—I have mislaid the address of a correspondent to whom I promised some seed of this Lily. Will he kindly communicate with me? *Herbert Maxwell, Monreith.*

RESULTS OF SPRAYING POTATOS DURING 1917.—There can be no doubt that during the past season much spraying of Potatoes was carried out, and many, like myself, who have been expected to advise, and in many instances to assume responsibility for carrying out the work on the new allotments, would, I think, welcome a summary of the results obtained throughout the country. It is possible that many have not had previous experience of Potato spraying, as it is known that much of this work was done rather late, due to the delay in the delivery of machines. They feel that their labour has been wasted, inasmuch as the spraying did not appear to have the desired effect, and, in many instances, to the surprise and annoyance of the holders, did not harm to the haulm. It is only fair to add that in such instances the injury caused was more likely due to the unhealthy condition of the haulm from attacks of aphids, or to the quality of sets used. It will, however, prove a difficult matter to explain away the injury to the satisfaction of those whose haulms suffered, and before another season arrives we certainly ought to be better informed than at present in order to combat opposition to spraying, and if proof of its value is forthcoming, pressure in some way should be adopted, because of the disappointments and doubts as to the efficiency of spraying, a summary of the results, together with growers' experiences and experiments with soil and manures, cannot be brought to public notice too soon or too conveniently, and any further efforts of the Board of Agriculture and the R.H. Society to obtain and publish reliable information from ascertained facts would be greatly appreciated. *Queen's Park, Crone.*

CORRECTION.—Probably my handwriting is accountable for the name of Mr. Todman being spelt Ludman in the note on "Raising Varieties of New Flowers from Seed" (p. 212). Todman was well known in the London District 40 years ago as a raiser of new flowers. *W. T.*

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—It has come to the notice of my committee that some members of the Society have been under the impression that they were not entitled to benefits while they were serving with the Forces, although they had kept their contributions paid. The committee would feel indebted to any gardener who would inform the secretary of any member who is either sick or wounded, that his case may be investigated with a view to giving him the benefits to which he is entitled. *L. C. Hill, Secretary.*

TYING MATERIALS.—There is likelihood of a shortage of tying materials. Strawberry runners make excellent ties, and they can perhaps still be collected in other gardens than mine. All my Endives have been tied with them, and many of the upper parts of the Tomatos. The sheathing spathes of Indian Corn-cobs make good ties for the latter purpose when split. Rushes may also be thought of. Some of the climbing plants have a tough fibre, and I find that the stems of the Chinese Yam are very strong. In France normally much tying is done with Osier, and it gives me more delight to receive a bundle of young trees tied up with this material than with the expensive manilla cord used by some nurseries. I cleared out some superfluous branches from some Lime trees in the summer, but the best—perhaps from the season of the year—did not seem any use. What treatment is needed? *H. E. D.*

HORTICULTURAL DIG-OUTS.—In your issue of November 3, p. 177 Mr. Rowles calls attention to the possibilities of dig-outs in the garden. It may be of interest to your younger readers if I give my experience of one I have had in use for 22 years. Living on the Surrey chalk hills since 1897, the idea soon

struck me that an underground chamber in the chalk would be an ideal place for Mushroom cultivation. In the early months of 1895 we had about ten weeks of real winter, and in looking round for something to keep the outside staff employed I determined to carry out my idea. I may say that the conformation of the ground here made the undertaking easy, the garden being bounded on the north by a sloping hill. Commencing operations, I drove a narrow heading straight into the hill till I came to the chalk formation. This consists of small lumps, hard, and not of the free nature; by freeing the bottom the rest would tumble down quite easily, leaving at the top what we call locally the "bullhead." This is the first layer of chalk under the soil, which, by the action of rain percolation, gets welded together like soft concrete, and therefore forms a natural roof. To make use of this I had to turn my tunnelling operations right and left, till I formed a chamber of some considerable size. To avoid accidents from falling chalk I had cut some stout planks of Oak; these were placed under the roof, and supported at intervals by cross-beams, these in their turn being shored up each side by stout props. The right-hand tunnel, being smallest, I partitioned off with a flint wall and doorway. Excavating the floor of this some 2 feet deeper enabled me to put in a bed of fermenting material, on which I was enabled to grow, in batches, sufficient Rhubarb and Seakale for the establishment, generally making my first cutting about Christmas. In my left-hand tunnel I made four beds 1 foot deep (leaving an 18-inch pathway), in which I grew Mushrooms in succession all the year round with more or less varying success, till the advent of the motor-car, and later the war, stopped the supply of the necessary materials. As the success of Mushroom culture largely depends on an equable temperature and on preventing an excess of cold air in the winter, I built up two walls, in my heading, roofing this over with concrete, and covering all over with soil. This formed a passage some 10 feet long, which enabled me to have a door at each end. By this means the temperature rarely went below 55°. One word of warning to those who may contemplate making a dig-out, and that is, it is absolutely necessary to provide for a gentle circulation of air by some means or other, or the tender tips of Seakale and Rhubarb will damp off. I also find that mine is not an ideal place for storing fruit or Potatos for any length of time. Chalk naturally holds a certain amount of moisture, which causes fruit to sweat unduly and Potatos to sprout. In conclusion I may say that if there are any young students interested enough to give me a call I shall be very pleased to show them my bomb-proof shelter. *W. Peters, Greens Gardens, Leatherhead.*

—The remarks of your correspondent, Mr. William F. Bowles, are both interesting and instructive. What he says as to using a kind of dug-out for gentle forcing purposes, and the adaptation to horticulture of devices used in war may be worthy of investigation and trial. One feels, however, that in his zeal for cheap contrivances he goes too far in the latter part of his article, when he imagines himself living happily at home in a kind of glorified dug-out or wooden hut. Now it is a dismal fact that the accommodation provided on private estates for both single and married gardeners in this country has, in many instances, left much to be desired in the way of dryness, light, and airiness. Mr. Bowles' remarks might well be taken by many who are responsible for the housing of their workpeople as an indication that a cottage or holly providing for dryness, light, and air is a superfluity, while such ideas condone the existence and use of such cottages as one can frequently see tucked away in corners of large estates—mere rabbit hutches, overhung with trees, and often damp. I agree that the men who return will have "quite different ideas of housing," but not, I think, in the way your correspondent means. The men from remote rural districts will have messed and conversed with those from the great centres of industry here and overseas, and one may, I think, hope that the fresh ideas gained will be progressive and not retrogressive, otherwise,

shuld there be many, and Mr. Bowles, that the idea of a modern building, as residence, the gardener of the future might be offered as remuneration for his energies, so much per week and so much ground when to "dig himself in" (which heaven forbid). S. J.

THE WEATHER IN SOUTH NORFOLK. The first snow of the season fell on Sunday, the 25th ult. Strong gales of wind blew from the west and north-west on the 23rd and 24th ult., and on Sunday afternoon we experienced a snow-storm of large flakes, followed at night by more snow, and by Monday morning some 2 inches had fallen, covering trees, hedges, and houses-tops. The last fall of snow in the winter 1916-17 occurred on the morning of April 15, 1917, when the ground was covered to a depth of some 2 inches. J. Batters, Gillingham, Norfolk.

THE LATTICE LEAF PLANT OUVIRANDRA FENESTRALIS.—In the obituary notice of the late Mr. William Marshall (see p. 202) mention is made of his successful exhibits at the International Horticultural Exhibition held at South Kensington in 1886. He also showed in the Miscellaneous Class a specimen of *Ouvirandra fenestralis*, which was of particular interest to me, as I had never before seen this singular plant. Introduced from Madagascar about ten years previously, it was at that time very scarce, and attracted great attention by reason of its singular, skeleton-like leaves. This specimen was commended. It may be of interest to note that in the class for ten exotic Orchids in flower, in which the 2nd Prize was awarded to Mr. Marshall the plants shown by him were *Cattleya Mossii*, *Cattleya Skinneri*, *Cypripedium villosum*, *Dendrobium Dalhousianum*, *Dendrobium densiflorum album*, *Dendrobium nobile*, *Dendrobium tortile roseum*, *Eriopsis rufidibullbon*, *Oncidium Philippianum*, and *Selenipodium caudatum*. It will be seen that there was not a single specimen of the now popular genus *Odontoglossum*. R. T.

AWARDS.

FIRST-CLASS CERTIFICATES.

- Cattleya Sara Queen* var. *Equanatum* (Mazdara *Hya de Coen* × *Crackelliana alba*), a large, white flower with distinct markings in the lip; *Sophio-Cattleya Theophrasti* (S. C. *grandiflora* × C. *Mendelii*), both from S. GRIVIER, Esq.
- Cypripedium John Hartley* (*Reginald Young Shogun*), from JOHN HARTLEY, Esq.
- Odontoglossum crispum Xanthotes* var. *The Gentlewoman*, from W. R. LEE, Esq.
- Laelio-Cattleya Myrtila* var. *Superba* (L. C. *Gottovina* × C. *Doriana*), from P. SMITH, Esq.
- Cattleya Folia Imperator*, from Messrs. SANDERS.

AWARDS OF MERIT

- Odontodia amabilis Ashworthii*, *O. punctatum* var. *Princess Maid*, *Cattleya labrata Prude* of *Southgate*, C. *Corona* (*Mantini* × *Hindiana*), C. *Lady Ashworth's* var. *varochii* × *oreum*, and *Fubata* (*Folia* × *Portia*), *Brasso-Cattleya Chetonia* var. *Ashworthii*, all from R. ASHWORTH, Esq.
- Cattleya Estera* var. *Madonna Dissoluta* (*Andrea* × *Harrisoniae alba*), *Laelio-Cattleya Aranda West Point* var. (L. C. *luniflora* × C. *Amersoni*), *Brasso-Cattleya Oberon Sanders*

FIG. 1. SEEDS OF WHEAT-LIKE CEREALS.

- var. *B. C. Diphysia Mossae* × C. *Schradiana*), and *Cypripedium Actaeae*, from S. GRIVIER, Esq.
- Cattleya Patricia Heathfield* var., and *Laelio-Cattleya Salscha* var. *Princess Patricia*, both from J. J. BATTERS, Esq.

CULTURAL CERTIFICATES.

FIRST CLASS.

- To Mr. E. ROGERS, for *Phlox Lospinnia*.
 - To Mr. J. LAW, for *Cattleya Patricia Heathfield* var.
- CORRECTION.—The *Laelio-Cattleya* exhibited by P. SMITH, Esq., at the meeting on October 15 is *Mitrona* var. *Davidrought*, not *Mitrona* var. *Davidrought*.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

NOVEMBER 12. The monthly meeting of this society was held in the R. H. S. Hall on the 12th ult. Mr. G. H. Curtis presiding. The ordinary week pay for the month amounted to £28 15s. 4d., State Section £24 16s. 4d., and maternity claims £5. The rules having been approved by the National Health Insurance Commission, the Juvenile Section is now open to boys of 12 years and upwards.

CROPS AND STOCK ON THE HOME FARM.

THE ELECTRIFICATION OF AGRICULTURAL SEED.

SELING the many uses to which electricity has been applied with beneficial effects, it is not surprising that attempts are being made to employ it for the purpose of increasing agricultural crops. In my opinion it is now fairly well established that in the near future we shall witness results from electricity of a startling and satisfactory character.

Some few years ago Mr. H. E. Fry, of Godmanstone, near Bathurst, who had for some years previously interested himself in high velocity electricity, turned his attention to the improvement of crops by the aid of electricity and various chemical solutions, the aim being to destroy the injurious bacteria and spare the useful ones.

The present idea, however, is to saturate seed grain to the electric current before it is sown, with a view to increasing its germinating power and stimulating growth.

The process consists in steeping the grain in various solutions in conjunction with certain reagents and chemicals before submitting it to an electrical current. The chemicals that are used are inexpensive and exist universally. Some of the solutions are provided by nature, such, for instance, as the radioactive mineral waters of Buxton, Bath, and elsewhere; sea water is also specially suitable.

Mr. Fry was fortunate in obtaining the valued assistance of the owner of the Godmanstone Estate for the carrying out of his experiments. The farm is hilly, some parts 300 feet above sea level, and not what would be in some counties called rich land, but quite an ordinary thin soil overlying chalk subsoil.

For thoroughly testing the advantage of treating seed corn and roots several fields were set apart last spring, all being treated in the ordinary way of rotation cropping without any special preparation in regard to manures.

In August last, whilst the crops were still standing, I had the privilege of inspecting them under the guidance of the bailiff, Mr. Smith. The first field examined was one of 20 acres, situated on an eastern slope, and sown with Black Tartarian Oats, half with treated corn and the remainder untreated. The previous crops were, 1914, roots, fed off with sheep, followed in 1915 with dredge corn, Oats, and Barley, with which was sown Clover and grass for a hay crop in 1916. In March of this year the Oats were sown at five bushels per acre.

On approaching the field I at once detected a difference in the greater luxuriance of the growth. On a closer inspection the straw on half of the field so treated was found to be 3 inches higher than in that untreated. Mr. Smith seized a handful of straw in quite a haphazard manner in both plots, treated and untreated. The comparison showed much difference in the thickness of the straw and size of the ears.

The next field inspected was 40 acres of Champion Yellow Hybrid Turnips. A five-mulder drill had been used for sowing the seed. The treated seed occupied every fifth drill. The difference in the appearance of the plants in this single row was very striking. The foliage on many of the roots was much more robust and possessed more chlorophyll than the untreated plants in the four remaining drills.

I pulled up roots opposite each other from the two rows, without any attempt to choose. That from the treated seed was distinctly larger. This did not follow down the whole of the rows, because in a Turnip field it is seldom possible to get an absolutely even plant, as in the ordinary thinning of the plants it often happens that the larger plants are cut out and the smaller left, simply because the larger are not situated quite at the right distance. The soil, too, varies considerably in fertility; some plants get away quicker from the soil.

We then crossed over to Northmore, a neighbouring farm, owned by Mr. Mole, who has taken an interest in the subject, and has sown two fields with treated and untreated seed. The barley was being cut. Here the untreated portion displayed less luxuriance of growth in the thickness of the straw, as well as in height and in the size of the ears.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

NOVEMBER 2. Present, Mr. E. A. Bowles, M.A. (in the chair), Messrs. W. C. Woodall, J. Fraser, W. Helys, and F. J. Chittenden (hon. sec.).

Planting of Blackberries.—Mr. Bowles showed fruits of *Vitis rotundifolia*, which frequently fruits in his garden, though less profusely this year than in the past seasons, and of *V. vulpina* now fruiting for the first time in his garden.

Wheat var. Carminon.—He also showed a specimen of the well-known Wheat var. *Carminon* where a multiplication of the bracts takes the place of the flower. (Our illustration (p. 225) is from a sketch made by the late Worthington G. Smith shortly before his death.) [Eus.]

Insect attack on leaves of *Tris Calceoloma*.—He also brought from his garden leaves of this *Podisidema* with the larvae and pupae of a mining Dipteron sp. Several of the larvae fed together in the leaf and pupate in colonies.

***Lophanthus* attacked by gall on stem.**—Mr. J. Fraser showed stems of *Loganberries* attacked by a gall on the stem, similar to those on the stems of Brambles and Raspberries, recently shown, and probably due to the attack of the fungus *Coniostyrium* sp.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

NOVEMBER 1. Committee present: The Rev. J. Crossbaldstone (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. C. Cowan, J. Cypriot, A. G. Elwood, J. Evans, P. Foster, A. Hamner, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, J. McNab, W. Shackleton, H. Thorp, and H. Arthur (secretary).

The Oats were sown in a field which had previously lain some years as derelict grass, and naturally was in poor condition before being taken over by the present owner. Here the difference in the treated portion was most striking in the height of the straw.

The whole of the headland on one side of the field was sown with the treated seed in March, but only half the field, the remainder being the same seed but untreated, the headland especially being a greater length of straw. The untreated part of the field was ripening earlier owing to the less luxuriance in growth.

The conclusions I drew from these inspections are that, to use a common phrase, there is "something in it." If by treating the seed only two more sacks per acre are produced, which is a low estimate, in value the two sacks are worth 40s., and surely the gain is considerable.

The treating of the seed costs about 14s. per sack of Wheat, 12s. 6d. per sack of Barley, 11s. per sack of Oats, plus rail carriage when treated at a depot; quite an inexpensive matter.

It is likely, too, that further progress will be made, as Mr. Fry has many experiments on hand, especially with vegetables, notably Potatoes. If in the near future something could be done to render the plant immune from disease what a boon that would be! The Tomato disease, too, is under investigation, and so is rust in Wheat, which has so harmful an effect on the crop results.

I might quote instances of success with the treatment of seed Wheat and various results, but prefer to confine my remarks to what I saw.

Formerly, the method of treating the seed is this:—In a tub 6 feet long, 2 feet 6 inches wide, and 1 foot 6 inches deep is placed seed—Oats, Barley, or Wheat. In this tub the various chemical mixtures employed are added. Electric wires are run through the bath connected with a dynamo for electrification. The different seeds are subjected to the current for various periods. For instance, Wheat requires 3½ hours, Barley 4½ to 6, Oats 4½, Mangold 3, Swedes and Turnips 1½ hours. The seed is then dried and sown as required.

The scheme of the Wolfryn Co., who have secured patents in the United Kingdom, the United States of America, and many foreign countries, is to encourage the erection of plants in various parts where electricity is obtainable, and treat the seed direct from the farms according to individual requirements.

Thus anyone with electricity at command and the necessary chemicals, can treat their own seed, by sanction, of course, from the patentees—E. McInerney.

ANSWERS TO CORRESPONDENTS.

ALPINE UNDER GLASS: *D. M. Broadstairs*.—Nearly all Alpine plants are suitable for growing in unheated glasshouses, such as yours, and are seen at their fullest beauty in a glass house owing to the protection afforded them. For an Alpine house any form of glass structure is suitable, and fire-heat is not required. Ventilation should be freely afforded, even in the depth of winter, for no true Alpine plant is affected by frost, overhead damp being the greatest enemy. The following plants are a selection:—Late autumn and winter flowering: Alpine Cyclamen in variety, especially *C. heuphlostium*; *Oxalis lobata*, *Scilla hispanica* and *S. alba*, *Draba aizoides*, *Gentiana aemula*. Late winter and spring: *Hepatica* in variety, *Achillea argentea*, *A. rupestris*, *Anemone alpina*, *A. narcissiflora*, *Adiantum* in variety, *Elymus graminifolius*, *Eriophorum carinatum*, *Gentiana verna*, *Gentiana argentea*, *G. cinerea*, *Linum alpinum*, *L. perenne*, *Phlox amoena*, *P. prostratum*, *P. verna*, *Primula* in variety, *Saxifraga* in variety. Summer bloomers: *Campulula* in variety, *Alpine Dianthus* in variety, *Androsace carnea*, *A. serotina* (Lambly), *Edithia delphinica*, *Gentiana montana*, *G. barba*, *G. rotunda*, *Linopseum prostratum*, *L. p. heavenly blue*, *Myosotis azorica*, *Oxalis emmer-hylla*, *Sedum* in variety, and *Sempervivum* in variety. Nurserymen who specialise in Alpine and rock garden plants will be able to supply the foregoing species. A necessary adjunct to an Alpine house is a cold frame or frames, in order to be able to store the pots

and pans safely during the non-flowering periods, and to give the plants what protection is required in damp, cold weather. Plants with leaves that develop down or med especially require protection from damp.

APPLES DISEASED: *Mrs. S.* The fruits are affected with spot disease. Spray the trees next spring with Bordeaux mixture just after the fruits set, and again three weeks later. Use a fine, misty spray, and take pains to spray the undersides of the leaves, as it is there where the fungus forms its spores, which infect the fruit.

CARNATION BLOSSOMS DAMAGED: *G. C.* The Carnation blossoms have been damaged by thrips, causing the petals to become speckled, and the flower to open imperfectly. Thrips make their appearance in the Carnation houses towards the end of the summer, and cause infinite trouble to the early bloomers unless dealt with promptly. Spraying with clear soft water is a good preventive during the summer, but fumigation with any suitable nicotine compound is the best remedy at this date; do the work on a still day, and when the plants are dry.

CHRYSANTHEMUMS: *B.* Chrysanthemum cuttings may be inserted at any time from now onwards until the end of March. January and February are the best months in which to propagate the decorative and single varieties. After the old plants have finished blooming, cut them down to within 8 inches of the pot and stand the latter in a light, airy position in a cool house till the time you propose propagating, when the cuttings (from 3 to 4 inches long) should be inserted in a light compost in either pots, pans, or boxes. The cuttings should be kept in a close frame having a temperature of from 45° to 50°. When they are suitably rooted, gradually admit air preparatory to affording the plants cool greenhouse or frame treatment. The old stocks should be discarded, as you suggest. A few good decorative varieties are as follows:—*Caprice* du Printemps, and its varieties, *Cranfordia*, *Market Red*, *Mrs. H. W. Thorpe*, *Mrs. J. W. Steeter*, *Source d'Or*, *Money-maker*, *Miss A. Brooker*, *Winter Cheer*, *Heston White*, and *Antocrat*; (Japanese) *Mrs. R. C. Pulling*, *Regd Vallis*, *F. S. Vallis*, *Lady Talbot*, *W. Rigby*, *Mrs. C. Drabble*, *Queen Mary*, *Mrs. J. Gibson*, *Undaunted*, *Salonica*, *Frances Joffie*, *Mrs. E. A. Tickle*, *William Turner*, *Mrs. H. Tysoe*, *Charlotte E. Soer*, *Bob Pulling*, *Mrs. A. F. Tofted*, *Louisa Pockett*, *Master James*, *Golden Champion*, and *Mrs. Algernon Davis*.

HYDRANGEAS: *E. B.* Plants of *Hydrangea hortensis* should be partly cut back after they have bloomed in August or September, and placed in a sunny position out-of-doors, where they should be allowed to continue to grow until the foliage shows signs of turning yellow, when they should be removed to a cool house or frame. They must be protected from frost. Plants that have become pot-bound should be re-potted as soon as they have broken into growth freely after being cut back. They will continue to develop roots all through the winter. Cuttings root freely if inserted in a frame in a compost made of leaf-mould and sand, say, during August, and if potted into 48 sized pots early in October, will develop good single heads of bloom from April onwards.

NAMES OF FRUITS:—In the naming of fruits, we desire to oblige our correspondents as far as we can, but the task would become too costly and too uninteresting if we had no restrictions. Correspondents should observe the rule that NOT MORE THAN SIX VARIETIES be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. The fruits should be kept separate, ripe, and they should be properly numbered, and carefully packed in strong boxes; cardboard is often smashed in the post. A leaf or shoot of each variety is helpful, and in the case of *Phoradendron*, *Peaches* and *Nectarines*, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. By neglecting these precautions, correspondents add greatly to our labour and run the risk of incorrect delay and incorrect determination. We do not undertake to send answers through the post, or to return fruits. Fruits and flowering plants must not be sent in the same box. Delay in any case is unavoidable.

T. L. Dovey du Combe, *R. W. N. 1*, *Scotch Bridget*; 2 and 3, *Brabant Bellefleur*.

4, *Mabbott's Pearmain*; 5, *Monarch*; 6, *James Grove*. (Thanks for 6d. for R.G.O.F. Box.)—*W. P. Apple Hubbard's Pearmain*, *Pear Beurre d'Angou*—*C. G. A.*, *Moor Park Pippin*—*J. B. POTATOS TURNING BLACK WHEN COOKED: *F. H. C.* Certain varieties of Potatoes grown on soils not perfectly suited to them are apt to turn black when cooked in the usual way by boiling. Try steaming them instead.

RICHARDIAS (ARUM LILIES): *E. B.* The plants should be hardened gradually after they have done blooming, and placed in the open, which will be from the end of April to the end of May, according to the flowering period. Water, or even liquid manure, may be freely given until the foliage shows signs of turning yellow, when water should be withheld gradually, and the plants turned over on their sides for a week or two. During August and before fresh rain have formed the plants should be shaken clear of the soil and re-potted in a rich and fairly holding compost. Afterwards place the plants in a frame to protect them from heavy rains for a time. Treated in this way, they do not make quite so much foliage, but bloom earlier than when planted in the open during the summer, lifted and re-potted in the autumn. You may not find it necessary to re-pot your plants every year; but every second season would suffice if the drainage is in perfect condition and a top-dressing of rich compost applied.

SEED POTATOS: *H. P.* The premature sprouting of the tubers in a clamp will not spoil them for seed if the sprouts are promptly rubbed off and others not allowed to grow again in the heap. The best way to deal with the tubers is to set them on end in boxes in a cool, airy shed or cellar, free from frost. In such conditions they will not commence to grow until the time of the year when the shoots would be at the right stage for planting such early varieties as you name. If they cannot be treated as advised, keep them in small heaps and turn them over occasionally, removing any shoots that form between the present date and January.

VEGETABLES GROWING ON HEAVY SOIL: *K. P.* You appear to have cultivated the plot in a very thorough manner, and, provided the road-sweepings are free from petrol or creosote, you can use them freely, as you suggest. In turning up the soil, leave the surface as rough as possible for exposure to the beneficial effects of frost. Apply the lime and basic slag now, and the sulphate of ammonia at the spring. The stable manure is best applied now; it will become thoroughly decayed by the time the plants are ready to make use of it. The leather-jackets and most of the wireworms will doubtless have disappeared next season. The ground crapped with Brussels Sprouts should be dressed with basic slag now, and afterwards treated as you propose. See article on p. 215.

REMARKS.-Brandy's Seedling, New-on Wonder, Dumb-bow, Seedling (working) and Cox's Orange Pippin selected form the bulk of the supplies of Apples. Several sorts of Cox's Orange Pippin are sold by the dozen, and those of lesser quality in half-sieves. In the apple trade, the demand for Gages shows a slight increase. The Alameda and its order of fruit are being killed or burnt. Oranges and Lemons are still very scarce and expensive. There is much better Tomato. Mushrooms show a slight increase in supply, not enough to affect the prices. Gimmey's Great Beans are a fairly good supply. Sticky tubercula (Cancer) Anthracis and Chorio is offered in limited quantities, but from all sources are realising high prices. A note of all plants are on what is left. The same list is given in our current list, printing with the exception of Cauliflowers and Cabbage. E. H. R. Covent Garden Market, November 28, 1917.

GARDENING APPOINTMENTS.

- Mr G Beale a Gardener to Geo L. Wood Esq. ... Mr John Busby a Gardener to the Rev. Admiral and Mrs L. ... Mr J. Clark a Gardener to the Messrs J. WALTER & SONS, 21, Abchurch Lane, the Auctioneer at New Gate Street, is Superintendent of the St. Adams Cemetery.

SITUATIONS WANTED.

IN PRAISE OF THE GARDENERS' CHRONICLE.

THE GARDENERS' CHRONICLE is the only gardening paper with seventy-six years of history behind it. It was founded in the dawn of what is commonly termed the scientific age. It has seen the rise and development of the railway, and its partial supersession by motor road-traffic; the discovery of the power of electricity, and its application to a bewildering multiplicity of every day affairs; the economic emancipation of women, and their entry into industrial life; and, last of all, the discovery of the flying machine—so long believed to be impossible. The GARDENERS' CHRONICLE has not remained static through all these marvellous changes. It has grown, developed, expanded. It has remained throughout its whole career completely in sympathy with its readers. It has advanced with them, explored with them the realms of experiment, examined with them in a spirit of intelligent sympathy every new theory of botanic or horticultural science, provided a medium whereby they have been enabled to communicate with each other and make their discoveries known. It is revered for its great age, yet respected for its modernity; it has the experience of years and the elasticity and progressiveness of youth. Through the storm and stress of the past three years it has stood unmoved, and it looks forward in full confidence to the enjoyment of the ampler scope and increased opportunities which the termination of the war will bring.

RIVERS'
Fruit Trees, Roses, Vines, Figs, Oranges, AND Orchard House Trees ARE OF First-class Quality.

A Large and Select Stock always on View.
PRICE LIST POST FREE ON APPLICATION.

THOMAS RIVERS & SON
Sawbridgeworth, Herts.
STATION: HARLOW, G.E.R.

"This is the rat that ate the wheat."
Thousands of tons of food are destroyed by Rats and Mice in our barns, fields, gardens and pantries.

LIVERPOOL VIRUS RATS & MICE EXTERMINATES
Harmless to human beings and domestic animals. No disagreeable smells as they come out of their holes to die.
In 24 hours prepared with bait for Rats 2 1/2 & 6/- for Mice 1/6. Of all Chemists.
Full particulars from **EVANS SONS LESCHER & WEBB, Ltd.** 56, HAZELTON ST., LIVERPOOL.

SUBSTITUTE FOR RUSSIA MATS.
"FRIGI DOMO" CANVAS.
Made from prepared Hair and Wool.
A good non-conductor.
2 yds., 3 yds., and 4 yds. wide
Price and pattern from—
BENJAMIN EDGINGTON'S,
DUKE ST., LONDON BRIDGE, S.E.

ORCHIDS,
Clean, well-grown and cheap; also Many Rare and Choice Varieties.
STOVE AND GREENHOUSE PLANTS OF ALL KINDS.

THE MARKET FRUIT GARDEN.

FORTUNATELY, November proved a comparatively dry month, which was welcome after the deluge of October. Only 0.58 inch of rain fell before the 26th, when 0.90 inch was registered, with 0.12 inch on the 30th, making the total 1.50 inch, which fell on eight days. The land, however, dried very slowly, and the digging of fruit plantations was not easy work. Nor could good work be done, as there was too much grass to turn in well—a legacy of the wet summer and the heavy rainfall of October, which rendered hoeing almost useless. Owing to the great shortage of male labour, women have to be depended upon mainly for digging. They do the work passably, considering the condition of the land; but they make it cost about double the amount paid to men at pre-war rates, and probably 50 per cent. more than would have to be paid to men now. Probably soldiers could be obtained to do the digging, but there would be the chance of inefficient men being sent, while there might be trouble in obtaining lodgings for them. As for the National Service women, I prefer to employ the local women, who work for me regularly during a good part of the year. Digging is not properly women's work, and, at the best, they are only makeshifts at it.

PRUNING APPLES.

In settling down steadily to the long pruning campaign, we find evidence of injury to the condition of those Apple trees which were unavoidably missed last season, in consequence of the shortness of labour. Shoots on comparatively young trees, which should have been cut back last winter, in many cases, have become thickly studded with fruit spurs, which will prevent the free extension desired. Further, there is a thick growth of slender laterals, crowding the interior parts of trees of free-growing varieties. The worst victims of last season's neglect are trees of Allington

Pippin, planted eight years ago. As a pruner this variety is my particular aversion, on account of its tendency to make slender growths studded up to near their ends with fruit spurs, forked terminals, and unnecessary laterals pointing in wrong directions. If I were planting a thousand fresh acres, I would not put in a single Allington. It fruits profusely in alternate years only, and, when it does bear, it requires a great amount of thinning. Moreover, it is badly subject to scab. The variety requires severe pruning until it has become well furnished with branches kept well apart, and most of the laterals, which it throws out in great profusion, should be cut off entirely. No artificial spurring is needed, as natural spurs grow only too thickly. The particular trees under notice were trained on these lines, and they had been growing as satisfactorily as Allingtons ever do grow, up to last year, when, unfortunately, they were among the minority of Apple trees not reached by the pruners by the end of the pruning season. Some Blenheim Pippins, also planted eight years ago, have likewise suffered from the lack of pruning last year, the long branches being thickly covered with fruit spurs, a feature not common with young Blenheims. But the variety is a vigorous one, and it will recover its tendency to wood growth after the severe treatment it has just received. By the way, some rows are on the free stock and others next to them on Paradise; yet there is no decided difference in the sizes of the two lots of trees, while the development of fruit spurs is as abundant on one stock as on the other. It is easy to make symmetrical trees of this variety, and it is a pleasure to prune them.

There is not much to do to Worcester Pearmain beyond the thinning out of shoots from the interior parts of trees. With me, this variety is a miserably poor grower. The only trees of it that have branched out well are some on the Paradise stock, all the rest being on the free stock. The former are growing in the lightest soil on the farm. The pruning of Cox's Orange Pippin is always a tedious operation, in consequence of the immense number of new shoots that have to be cut out or spurred, and many more requiring to be cut back below scab-infected wood.

In dealing with Lane's Prince Albert, the main object is to cut back so as to promote extension growth, to secure which there should be no hesitation in sacrificing fruit spurs when the trees are dwarfed, as they are too likely to be. This variety should be pruned severely for some years after planting, in order to force vigorous wood growth before fruiting comes to exercise its dwarfing effect.

INSTRUCTIONS IN PRUNING.

The details of pruning cannot be taught by printed instruction. The variations necessary in practice are too intricate. Only general principles can be laid down safely as rules to be followed. Even in the case of trees for the first three or four years after planting, no

precise instructions are infallible. Varieties of a robust habit of growth require much less severe pruning than those of a feeble habit. There is no fear of the former fruiting prematurely, as there is of the latter. In nearly, if not quite, all pruning instructions a grower is advised to cut to a bud pointing outwards. This is right on the occasions of the first cutting back of freshly planted trees, and it is usually right in the second season. After that, the extension growths of trees of a drooping habit of growth often need to be pruned to buds pointing upwards; and this is quite commonly the proper proceeding among older trees, particularly after the weight of fruit has caused the branches to bend downward. Even among spreading trees planted only eight years ago, most of the cutting this season has been to buds pointing upward, though occasionally a sideways direction is desirable. The only universal rule is to cut to a bud pointing in the direction in which extension growth is desired. With varieties of an upright habit of growth, however, cutting to a bud pointing upwards is the rule to be observed. These remarks apply to Apple trees; but the case is similar with Plums, Victorias, for example, with overhanging extension growths, need to be cut to buds pointing upwards almost invariably, while with Monarchs cutting to buds pointing outwards is almost as generally advisable.

MISSRAPEX APPLES.

There is a larger proportion of distorted Apples among a few varieties this season than I have ever seen before. This is strikingly the case with Bramley's Seedling. The fruit of this variety is generally of good size, and much of it is quite large and of an extraordinary beauty of colour. But among the fruits this season, large and small alike, there are some of the ugliest of shapes, caused by deep clefts, often two or three in the same fruit. That the cause was injury to the surface of the Apples in their very young state by the bite of some insect is almost certain. The capsid bug is known to cause such deformity, and the bites of caterpillars are also believed to have a similar effect. The capsids sent from my place for identification in previous seasons have been declared to be of species regarded as harmless. But it is reported that capsid injury has been serious this season in places where it has not been noticed before. A curious point, however, is that capsids found this season when search was being made for Apple suckers were much fewer than usual. Caterpillars, as every grower knows, were very much more numerous than they commonly are. But Bramley's Seedling was much less seriously attacked by caterpillars than were many other varieties; yet it has suffered more than any other from the bites of some pest, that have caused contortion in shape. When the skin of a fruitlet has been pierced by an insect, the wounded spot does not swell in unison with the rest of the Apple, and, in consequence, a deep cleft is left.

CAUSES OF APPLE-ROTTING.

Messrs. Brooks and Cooley, in the *American Journal of Agricultural Research*, enumerate no fewer than ten micro-organisms which cause the rotting of Apples in store, first living as parasites, and only becoming saprophytes when the increased growth of their mycelium permits them to find, in the decomposed tissues, the substances necessary to their development. The researches of the writers were extended so as to cover the various temperatures at which the several micro-organisms could develop and attack the fruit; but, as all but two of them, when inoculated into the pulp of healthy fruit, grew normally at freezing point, while we are not told how much below 32° F. it would be necessary to keep the temperature of a fruit room to secure safety from attack, further enlightenment is desirable. The question is, Whether a sufficiently low temperature could be maintained without freezing the Apples? *Southern Grower*.

TREES AND SHRUBS.

WINTER-FRUITING TREES AND SHRUBS.

I HAVE never before seen such a wealth of fruit on ornamental trees and shrubs as is the case this year, and consequently the out-door gardens in winter were never more attractive than they are this season. Many of the newer introductions, especially from China, are providing us with a fine touch of colour, and from this point of view alone are great acquisitions, whilst the American species and varieties of *Crataegus* must be seen to realise their true worth. I am venturing to send the Editors a few sprays of various kinds and varieties, gathered on November 29.

A few that strike me as among the most beautiful are *Berberis aggregata*, *B. orthobotrys*, *Celastrus acuminatus*, *C. rugosa*, and *C. scandens*, simply laden with their bright fruit. *Cotoneaster salicifolia rugosa*, *C. species*, *Forrest*, *C. Zabelii*, *C. frigida* (Aldenham variety), and *C. divaricata*.

Crataegus monogyna fructu-luteo is covered with its bright yellow fruit; *C. monogyna foliis var.*, and *C. chipmewaensis*, are very beautiful, as also is *Acanthopanax Henryi*. *Eucnymus europaeus fructo-albo* is remarkably effective, and should be grown much more largely than it is. *Hippophae rhamnoides* (Sea Buck thorn) was never before so beautiful here. *Pyrus Malus aldenhamensis* is most distinct and beautiful. *Rhamnus erythroxylon* is covered with its fine, black fruit. *Pyraeantha Gibbsii*, in my opinion one of the finest berried plants in existence, *Stranvesia Davidiana* and *S. undulata* are both grand plants. *Symphoricarpos racemosus laevigatus* (the new Snowberry) is a delightful addition, and very conspicuous amongst other shrubs.

Many of the new *Viburnums* are a magnificent sight, *V. ovalifolium* being one of the best.

What an opportunity this bountiful fruit yield affords all who are interested in this branch of horticulture to increase their stocks by collecting seeds and raising them personally. To watch these germinate and grow into effective specimens must surely be one of the real pleasures of life to all who care for beautiful trees and shrubs. For the benefit of those intending to do this, I would say that I have found it best to sow the seed immediately the ripened fruit is gathered, and raise the plants in cold frames. *Edwin Beckett*.

PETREA VOLUBILIS.

THERE is a fine specimen of this twiner in one of the glasshouses at Holland House, Kensington. It covers an area of the roof measuring 20 to 25 feet by 8 feet, being wider than high, owing to the method of training. The stems are of considerable thickness, showing that it must be an old plant. It is very handsome when in bloom, the flowers being furnished with a

petaloid calyx of five long blue sepals and a violet corolla. The sepals are showy long after the corolla-drops, as in species of *Clerodendron*, which also belong to the Verbenaceae. In the genus *Petrea* some of the species are erect or arborescent habit. The plant flowers at various periods of the year, apparently as a result of differences of temperature. Mr. Dixon, the gardener, says it sometimes blooms in February, but is best in March. Last year it was at its best in May, and this year it was later still, owing to less artificial heat being given and to the severe winter. The species forms the subject of the supplementary illustration in *Gard. Chron.*, Jan. 13, 1906. The genus was named in honour of Robert James Lord Petre, and the name is often spelt *Petraea*. *J. F.*

ABIES BALSAMAE MACROCARPA.

A note in *Gardening* (Chicago, Nov. 1, 1917) states that Mr. A. D. Hill, whilst travelling in

LOST NAMES OF SEEDS IN EIGHTEENTH-CENTURY CATALOGUES.

The remarks by Mr. Roberts (p. 150) on an 18th century catalogue awaken a sense of long-forgotten or obsolete nomenclature. The distinguished writer himself acknowledges the difficulty experienced by anyone wishing to understand the stocks of seed of that period, and what is meant by the various names.

I have found by studying my earlier gardening works the modern equivalents of some names of seeds mentioned by Clarke and others.

THE TOKER BEAN. This is very obscure. I have never seen it nor anyone who has. It appears in almost all the early lists. It may have been derived from Tokat, in Turkey, as we had a Bean a few years ago called *Sword* or *Turkey*, which was a long-pod, and the Toker was classed

FIG. 86.—*POSOQUERIA LATIFOLIA* FLOWERING IN GLASGOW BOTANIC GARDENS.

northern Wisconsin, has found this handsome form in a wild state. It is characterised by long needles, large cones, dark foliage, and by the fact that even old trees hold their lower branches, characters which make of this variety one of the most beautiful of Firs.

POSOQUERIA LATIFOLIA.

The plant illustrated in fig. 86 will be best known to the majority of gardeners as *P. revoluta*, the leaves having revolute margins, but the correct name is *P. latifolia*. The photograph was taken in the Glasgow Botanic Gardens, and is sent us by Mr. Whittton to show how well the species flowered during the past summer in one of the glasshouses. The genus *Posoqueria* consists of about twelve species, all natives of tropical America. Like most members of the Rubiaceae, they have white, sweetly-scented flowers, with long corolla tubes

with the Windsor type. Switzer spells it *Stoker*, and Miller, *Tokay*.

BOGGOLE or BORECOLE, with "neighbour" and *Boorman* (an old Kentish family name), remind us of earlier ties with our gallant cousins in South Africa.

BOG BEAN is *Faba*, and has no relation to the *Buck* or *Bog Bean* (*Menyanthes trifoliata*). It is identical with *Dwarf Fan* or *Cluster* of the gardens; it was strongly recommended about 1760 for marsh and bog lands, the tall varieties requiring strong, clayey loam. It bears well, and has erect pods. The *Menyanthes* is an aquatic plant, intensely bitter, and has been used instead of rennet for coagulating milk.

BRUCCOLI: PURPLE AND WHITE. Switzer reports three kinds growing in his garden at Vauxhall, and gives an interesting account of his having procured the seeds from Italy. Many garden seeds were imported, as now, from that country, and, not having English names for them, they bore names in Latin, as *Brassica*

capitata. I have seen such paper labels pasted on old seed drawers. Several had the word Capitata contracted to Cap, which no doubt led to the name of "Cape" to Broccoli and Savoy. The first Broccoli and Chou de Milan (Savoy) were Sprouting varieties.

BUCKWHEAT, or BRASK (*Polygonum fagopyrum*). The specific name is derived from the likeness of the seed to Beech nuts, although only about one-third of the size. Cakes are made from the flour in the United States, but here the seed has been only used as pheasants' food.

KIDNEY BEANS, Dwarf and Tall. Nearly all the dwarfs have a tendency to produce running varieties, or "rogues"—for example, Canadian Wonder, and its now popular climbing form. We might include Scarlet Runners as French Beans, but the French call them Haricots d'Espagne. They are herbaraceous.

BURNET (*Poterium Sanguisorba*) is the small salad, or Sheep's Burnet, and quite distinct from *Sanguisorba officinalis*, a marsh plant, and a very shy seeder, often infertile.

CARDUS BENEDICTUS was formerly used to cure cancer, but long since discarded. The old name of *Cardus sculentus* (Eating Thistle) appeared in some lists. It was in all probability the Spanish Chardon (now Cardoon). It is described as a wild species or kind of Artichoke.

LOVAGE (*Ligusticum scoticum*), very frequent on the rocky coasts of Scotland, was reckoned a good emmenagogue. It has now dropped out of cultivation, and is rarely seen except in botanical collections.

MUSTARD, Black or Brown. *Sinapis nigra*. This is still cultivated, like the white, in the Eastern Counties, and formerly in the North, where it was known as Durham Mustard. The seed of the black species looks more like Turnip seed, and is very pungent. The white Mustard has yellow seeds; the flowers of both are yellow.

FINOCHIO, or ITALIAN FENNEL. The foot stalks at the base of this plant fold up like Celery. These overlapping pedicels become quite solid, and when boiled they form a very agreeable dish, but, like boiled Lettuce, have not been popular with British cooks.

HUMBLE PLANT (*Mimosa pudica*).

SENSITIVE PLANT (*Mimosa sensitiva*).

POMPIONS and PUMPKINS were represented by what the Americans call Squash. Gourds were mostly edible, the mammoth Pumpkin and ornamental gourds of various shapes were also cultivated. Loudon says the Pompon was the Melon or Melon of our early horticultural lists, the true Melon being formerly distinguished by the name of Musk Melon. The Vegetable Marrow came later from the Levant.

POPPLES (*Papaver somniferum*) (white seed) were grown for the heads or capsules, and the blue seed as maw for birds.

SMALLAGE, or WILD CELERY (*Apium graveolens*). The name Smallage for the plant that was the original of the garden Celery was retained in gardening books of the early 19th century.

PEAS. Just as it is common now for growers to apply "Marrow" and "Marrowfat" to blue-boiling Peas, so many round varieties bore these descriptions, but the terms Marrow or Marrowfat in the modern sense to wrinkled Peas could not have been applied before Knight's Tall White Marrow, the first of the new race of wrinkled Peas. It was produced from a very remarkable crossing of a small, round, white garden Pea and an earthy coloured tall variety with purple flowers, almost like a grey field Pea, but quite distinct; probably this variety may still be found here and there in the neighbourhood of Hereford by the name of Grey Jack. It has a nice, marrowy taste, and is much liked by cottagers.

To those who may be interested in the Mendelism of the wrinkled Pea, I would refer them to a small 8vo work published at Ludlow in 1802 by T. A. Knight, entitled *The Apple and Pear*. Wrinkled Peas when dry are no good as boilers.

They seem to contain less starch, or the grape sugar develops too quickly.

READING; PEA is a misnomer; it should be Reading, or Essex Reading.

Switzer, in his Compendium, 1751, writing about this Pea, says "not Reading, as by some falsely so called." It was similar to the old Hot spur of Early Emperor type. *J. Morrison.*

APPLE WILLIAM PETERS.

THE Apple illustrated in fig. 87 was exhibited by Mr. W. Peters, Givons Park Gardens, Leatherhead, at the autumn fruit show of the Royal Horticultural Society, held on October 9, and gained an Award of Merit from the Fruit and Vegetable Committee after a deputation had seen the variety in growth at Givons Park. It is a seedling from an extra large fruit of Cox's Orange Pippin, and in general appearance is a little suggestive of smooth, moderate sized fruits of Blenheim Pippin. It is probably at its best at the middle of October, when we found it to possess a very rich, vinous, and agreeable flavour. We give the following descriptive details: Eye open, set in a deep basin of even shape; calyx segments long and spreading; stamens median, tube cordate; stalk 1 inch long, thin, and set in a medium sized, even cavity; cells round, axile. Skin when ripe greenish yellow, with broken stripes of bright red on the side exposed to the sun, marked with spots and patches of grey, and a few specks of russet; flesh greenish yellow, very tender, juicy, sweet, and of good flavour. Foliole small, ovate, acuminate, much serrated; the tree is fruitful in a young state on the Paradise stock.

FIG. 87. DESSERT APPLE WILLIAM PETERS.

ORCHID NOTES AND CLEANINGS.

NEW HYBRIDS.

Flowers of the following three new hybrids have been sent to us by Mr. FREDERICK J. HANBURY, Brookhurst, East Grinstead:—

LAELIO-CATELEYA LYDIAEVA (L. C. Lydia (C. Gaskelliana) x L. C. Cowanij) and C. Dowiana aurea).—A very pretty flower of bright chrome yellow, the lip veined and tinged with orange, the wavy-edged front lobe ruby red, and the exterior of the side lobes a lighter shade of the same colour. *Laelia Cowanii* combines with C. *Dowiana aurea* in fixing the bright yellow colour, but there is no trace of the rose and purple of C. *Gaskelliana*.

CYPRIPEDIUM MISS RUTH BONSALE (C. *Acteas* Drucei's variety (insigne x *Lecanum* var.) and C. Miss A. Audrey Locke (Garret A. Hobart x *Troilus* var. Amy Moore).—Following a very good strain in which C. *insigne*, C. *Spicerianum* and C. *villosum* are blended, the present hybrid has a large and finely formed flower. The dorsal sepal is nearest to a large, light form of C. *insigne*, the broad petals, lip

and stamens resembling C. *villosum*. The broad, upper sepal is white, with a gamboge-yellow base having numerous dark purple blotches extending upwards into the white above. The sepals and petals are whitish-yellow tinged with purple.

LAELIO-CATELEYA MRS. R. P. MURRAY.—A very effective hybrid of light colour and attractive form, raised between *Laelia pumila* pumilans and *Laelia Cattleya* 1851 *L. toebrousa* x C. *Leopoldii*. The flower, which is 4 inches across, has nearly equal sized sepals and petals of bright rose purple colour, the petals having also a veining of darker reddish purple. The lip, which has the tubular form of the *Laelia pumila* section, with the margins folded over the column

in the lower half, is white tinged with rose at the base, and the front and margins of the recurved side lobes are bright ruby purple. There are several raised lines running from the base to the yellowish-cream disc of the lip.

JABOROSA INTEGRIFOLIA.—This plant is exceedingly attractive when in bloom, but those who have cultivated and flowered it find that its reputation for tenderness is only too well founded. In a sunny nook, in dry, leamy soil, it is very fine indeed. Its height varies from 6 to 12 inches, and above the broad leaves are shown the handsome, white, tubular flowers, about 2 inches long, and sweetly scented.

ON INCREASED FOOD PRODUCTION.

GARDENS AND ALLOTMENTS.

MUCH has been written on the necessity of making the most of labour and capital, but not much has been said and still less has been done in the direction of making the most of our limited supplies of land. The need for a more rational utilisation of this third great agent of production is clear. Notwithstanding that there is land available, and that there are thousands of men and women anxious to work that land, we see every day large areas on municipal out-kirts only "extensively" tinned and paying a rent of 20s. to 30s per acre. We have, on the one hand, multitudes dwelling in a wilderness of bricks and mortar, and on the other hand acres of land "extensively" and inadequately utilised. It is estimated that there are 750,000 war gardens or allotments now in this country. If 750,000 persons can be found with sufficient enthusiasm to work allotments, how many would be willing to work in real gardens attached to real homes? For the tremendous superiority of a garden attached to one's home, as compared with a mere allotment, needs not to be emphasised. These willing workers and these acres must be brought together. Everyone would benefit, including the landowner.

In the first place the municipal authorities of a town should have control of the land on the outskirts, i.e., the municipal "fringe," and they should be enabled to acquire it on equitable terms, that is to say, in most cases as purely agricultural land, and not with a heavy burden of "unearned increment" tacked on to the price. Probably the powers given under recent Small-holdings Acts would be sufficient. This fringe should be made as extensive and accessible as possible by improved travelling facilities. It is surprising how very unevenly population is distributed, even in this country. On the one hand there is the overcrowded city, while a few miles out one might imagine oneself in the wilds of British Columbia.

The ideal to aim at should be the provision of at least $\frac{1}{2}$ acre with each home. In a town with a population of 100,000 we may suppose that there are 20,000 households, of which at least half will be office or factory workers. Ten thousand houses with $\frac{1}{2}$ acre each will require 2,500 acres, exclusive of roads. A town of this size should have a municipal fringe of many times this extent. On a quarter of an acre it should be possible to produce vegetables and fruit equal or nearly equal in value to the rent paid for house and land. Thus the householder, by some expenditure of his spare time, would live practically rent free. It might be possible in many cases to have holdings $\frac{1}{2}$ acre in extent, or even more than this, thus providing a progressive scale for the ambitious, offering finally the possibility of ownership under certain conditions. "Give a man the secure possession of a black rock and he will turn it into a garden," said Arthur Young. The provision of sufficient land to pay the rent by spare-time gardening would introduce a fresh factor in municipal finance.

This combination of industry and horticulture might form the beginning of an industrial system wherein a man could work at two occupations, involving the highest economy of labour and reducing some of the disadvantages due to the monotony of ultra-specialisation and division of labour.

Another result would be that the food supplies of the country would be greatly increased. It is said that the world is now racing with starvation. Sir William Crookes, in 1908, said that we should soon be in a deadly peril for lack of food. Grossly exaggerated and unduly alarmist these statements may well be, and merely uttered for dramatic effect. Nevertheless we cannot afford to neglect any means for

increasing the home supply of food and making the most of our land. W. G. C.

POTATO WINDSOR CASTLE.

I AM quite in agreement with Mr. C. Davis (p. 196) when he says that the above Potato is still to be reckoned with for cropping, exhibition, and quality. This had a First-class Certificate in 1895, and has stood the test of time well. As for cropping, it varies from good to very heavy. I have watched enthusiastic and highly successful exhibitors carefully cultivating it, lifting the crop when mature, selecting the most shapely tubers, sponging them with water and then wrapping them in tissue-paper to wait the eventful day of the exhibition, so I know it is a handsome Potato for the purpose. Nearly all of the big nurserymen and Potato growers' catalogues I have list it as a second early, which, in my estimation, means mid-season—say, in the middle of August to the middle of September, earlier or later, according to soil, season and district. To get the flavour of a new Potato the tubers may be lifted earlier, if large enough. I never dig up a plant to see if the tubers are sufficiently large, but scrape away the soil and see how they are progressing. No doubt Windsor Castle is more subject to disease than for merely, but even a big market grower will prefer to risk a little loss from this cause than to grow a poor cropping variety with few good qualities to its credit. J. F.

WINDSOR CASTLE Potato, when grown as an early variety, sprouted in boxes or trays, and planted out at the end of March, is ready to lift early in July. The flavour, on our light land, is excellent. Having tried during the past 16 years as many as six new early varieties in one year, I can safely say I have no better early Potato for June lifting or for forcing in pots or frame than May Queen. It is my best-flavoured variety. I know two other sorts that run it close in coming to maturity, but when judged by flavour (without the Mint) May Queen comes out on top. Duke of York and Windsor Castle follow next according to season and the condition of sprouting of the sets. This year, 1917, Epineure was planted as second early (as both of the above-named varieties were scarce), and yielded well at the rate of 2 cwt 1 lb. from 50 square yards, and in the whole half hundred-weight of seed not one was larger than a Walnut; they were much shrivelled and dried, but responded well to generous treatment on newly broken up grass land, as did Dalhousie, which returned 10 tons to the acre with similar treatment, all the work being hastily done as a national necessity to provide food. Our cricket field, used for a review of the V.T.C. on Easter Sunday, before Whit Sunday was cropped to its fullest extent. J. G. Wilson, *Cherry Park Gardens, Wakefield*.

GROUND OPERATIONS.

It would be interesting if Mr. Davis would try the system I call "ridge-trenching," which I described some time ago (*G. C.*, 4, iii, 16, p. 136). With simple ridging about half the area of the second spit is exposed; with the ridge-trenching the third spit is only covered by one spit. If time permits to add the trenching to the ridging I shall add lime and matured ashes to the third spit. H. E. D.

BULB GARDEN.

AUTUMN CROCUSES.

In regard to the remarks on autumn Crocuses printed on p. 212, I may say that I have given up the cultivation of these Crocuses here in Hereford—they make splendid leafage, and then there are a few or no blooms which rarely last more than a day; they do not seem to like our damp mists. A year or two back I was amazed to see what a show they made in a garden at Reading. I have tried about 10 species. H. E. D.

THE KITCHEN GARDEN.

By J. DUNN, Foreman, Royal Gardens, Windsor.

EARLY POTATOES.—A few Potatoes may be forced in heated pits. If the sets have been placed in boxes to sprout they should be planted before the shoots have grown very long, or they will be liable to injury. The material of the old hot-bed should be removed, and a quantity of freshly fermented leaves substituted. Let them be packed tightly together to provide a mild and lasting warmth, and cover them with soil to a depth of 9 or 10 inches. When all the material of the new bed, including the soil, is warmed by fermentation, plant the tubers, allowing them plenty of room. If only a small number of New Potatoes is required the forcing may be done in pots, which should be well drained, and half filled with light, rich soil, thus allowing room for subsequent top-dressings. The temperature of the house or frame should be 55°. Place the pots near to the roof-glass.

FRENCH BEANS.—Make a sowing of French Beans in 7 inch pots, with a view to obtaining a supply of pods in February. Successional sowings made at intervals of ten days will maintain an unbroken supply of Beans. The pots should be placed not more than 18 inches from the roof-glass. A night temperature of 60°, rising to 70° by day, with sun and a moist atmosphere, are necessary. Plants which are producing pods should be given weak liquid manure from the farmyard. On bright days the foliage should be lightly syringed to keep red spider in check.

SEAKALE.—There should be no difficulty in forcing Seakale from now onwards, and batches of roots should be placed in warmth at intervals of eight or ten days. Grow the roots in perfect darkness and in a moist atmosphere in a house or shed having a temperature of 60°. As the roots are lifted for forcing, young, straight things of suitable size should be selected and prepared for next season's stock. Let them be cut into 7 inch lengths and laid in a horizontal position closely together in a light, sandy border, and covered with the soil to a depth of 4 inches. Protection from severe frost is necessary, and this may be provided by placing sifted ashes over them to a depth of 4 inches. The cuttings will be ready for planting in the beginning of April.

CUCUMBERS.—Make a sowing of Cucumber seeds in small, clean pots, to obtain seedlings for planting out early in the new year. Use soil that is moderately moist that will not require moistening again until the seeds germinate. Mice should be guarded against by placing sheets of glass over the pots as soon as the seeds are inserted. Cucumber plants in forcing need careful attention; all decaying leaves and shoots should be removed, as these harbour red spider. Keep the atmosphere of the house moist by syringing the walls and floor several times daily, and syringe the foliage lightly in fine water. Do not allow the plants to become overworked, which would necessitate the removal of large quantities of foliage at one time, and cause a check to growth. When watering the roots, moisten the whole of the soil. The application of light top-dressings of loam and leaf mould in equal parts on frequent occasions will do much to keep the growth clean and healthy. The temperature of the house at night in mild weather should be 70°, but in very cold weather it may be allowed to drop to 67°. Open the ventilators a little on sunny days, but not sufficient to expose the plants to cold draughts.

FRUITS UNDER GLASS.

By JAS HUDSON, Head Gardener at Gunnersbury House, Acton, W.

OLD AND EXHAUSTED VINES.—Vines that have become exhausted through old age or other causes may be rejuvenated by cutting them down and training in young growths as new rods.

This treatment is applicable to all vines, whether early, mid-season, or late. I have recently practised it with distinctly good results in the case of late vines. Such treatment offers an excellent opportunity of ridding vines of insect pests, especially where they have been persistent and difficult to eradicate by other means. I have never been troubled with mealy bug on vines, but it is one of the worst pests the indoor gardener has to contend with. In *Gard Chron.*, Jan. 6, 1917, p. 4, I dealt with the treatment of vines that were infested with such pests. Such drastic measures as cutting down the vines afford opportunities of dealing with the border in a thorough manner. I remember in my younger days some old vines that, with one exception, were all rooted out, the one left being at the end of theinery. The border was chiefly outside the house, only about 3 feet being inside. All the material of the outside border was removed, and all this old vine had to grow in was the inside border. With the making up of the new border, however, it quickly put on renewed vigour, and was in bearing again before the young vines that were planted.

COVERING OF VINE BORDERS.—I do not advocate the covering of vine borders to any great extent. A light covering of leaves, or a top-dressing with farmyard manure, may, however, be used with advantage. By this I chiefly mean the use of fermenting material for early forced vines. A border that is compactly inserted into the house is to be preferred for early forcing. In cold districts, or where it is known that the border becomes excessively wet in winter, it pays to cover it with corrugated iron sheeting or spare laths. In doing this, however, see that the rainfall is carried off completely from the border, or matters will not be improved. Before the covering is placed in position, give a light top-dressing of rich loamy soil, and if the vines have borne a heavy crop, add a sprinkling of vine manure.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to the Hon. ARTHUR J. DAVEY, Abbots Wood, Colindale, Surrey.

TRAINING WALL TREES.—Defects in trained trees are apparent as soon as the leaves have fallen. The shoots or branches of horizontally trained trees need to be nailed at regular intervals of space, which are easily measured on walls where the lines of bricks are visible. Other wise, a chalk line or similar means should be adopted. This, of course, would chiefly be necessary for beginners, of which there are a good many, even in the best gardens this season. The branches should be trained about 14 inches apart, which will equal about three courses of bricks. Fan trained trees are very useful for forming into large specimens. A good wall of horizon tally trained trees is also a good feature in any garden; Pears are especially suitable for this purpose. The bottom branches of the fan trained tree should be practically horizontal, the next ones at a very slight angle, and so on, till the whole fan is formed, with the central branch in a vertical position. These trees should be now pruned and trained as fast as opportunity permits. Any scions required for grafting in the spring should be collected, labelled, and well "heeled" in on a north border.

PLANTING.—All kinds of fruit trees and bushes may still be planted in mild, dry weather. The Bullace and Damson should not be omitted, as these fruits are most useful. They do well, even in hedges, and can be planted to form the boundary of an orchard, thus serving a double purpose. The fruits are often found useful when the Plum crop is short. Shepherd's Bullace has large, green fruits; Black Bullace is a very late variety, and excellent when used with Apples; Veitch's Bullace is a very prolific bearer. Among Damsons, Bradley's King (sometimes called King of Damsons), Cheshire, and Frogmore are three desirable varieties.

SPRAYING AND MANURING.—Fruit trees may now be sprayed. Choose a calm day for the operation. Grass grown orchards may be much improved by manorial dressings.

FRUIT ROOM.—Examine the fruits regularly, and remove all decaying specimens.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

PERPETUAL-FLOWERING CARNATIONS.—Carnations are some of the best of winter-flowering plants, and can be grown with very little fire-heat. The main batch of winter-blooming plants is now at its best. To keep both plants and blooms in good condition, abundance of fresh air in all but the most inclement weather is necessary. If the weather is fairly dry and bright, scarcely any fire-heat need be used; in very damp weather a little warmth will be required. Under normal conditions the night temperature should be from 47° to 52°, but there is not the slightest danger if the temperature of the house drops 10 or 12 degrees lower on cold nights. Codling is very injurious to Carnations, and they are easily damaged by excessive fire-heat. Watering should be done fairly early in the morning, so that all dampness is dispersed before nightfall. If little or no fire-heat is used the plants need not be watered more than two or three times a week. When watering, be sure to fill the pots quite full, thus ensuring the whole of the soil in the pot getting watered. If signs of Carnation rust are seen every infected leaf should be cut off and burnt, but do not spray the plants at this season. Rust is sometimes caused by too much heat and moisture; overfed plants are also very susceptible to disease, as the growth under such conditions is apt to be soft and flabby. During the next few weeks artificial manure should not be given. If any difficulty is experienced in finding sufficient room for the plants, sooner than crowd them to gether place some in a fruit house at rest, such as ainery or Peach house. The conditions there will suit the plants, and though, if the weather is severe, the blooms will not open very fast, those which do develop will last a long time, and the plants will remain vigorous for blooming in the spring. Half a dozen excellent varieties are May Day, Triumph, Mary All-wood, Salmon Enchantress, White Wonder, and Mikado.

SOUVENIR DE LA MALMAISON CARNATIONS.—

For old plants of Malmaison varieties may be wintered in cool houses, the principal points to be remembered in these conditions being, first, that they should never be watered unless quite dry, and, secondly, that they need an abundance of fresh air. Growth is now practically dormant, and the grower need not be disturbed if the thermometer in the house should register a few degrees of frost; it will not harm the plants. After such a rest they will start into growth very strongly in the spring, when more water and some stimulants can be given. This year's layers, if well rooted, can be potted into trench pots. Unless well rooted, however, they should be left over till the new year; there is then less danger of overwatering than if potted now.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart, Gatton Park, Reigate.

CYPRIPEDIUM. Cypripedium colorado, C. niveum, C. Gold-Froyae, C. bellatulum, and the many hybrids of these plants should receive very careful treatment in winter. They all have thick, fleshy leaves, and do not require so much moisture at the roots as other Cypripediums. The compost should become quite dry before water is applied, when the receptacle may be immersed nearly to the rim, or the water may be poured around the outer edges of the compost to prevent moisture lodging in the axis of the leaves. Take care that water dripping from the roof does not fall on the foliage. In removing the flower-stems cut them out clean to the base, for if any portion of the stalk be left it sometimes sets up decay, which soon proves fatal to the plants. Other Cypripediums of the flat-leaved section, including C. Leachii, C. Rothschildianum, C. laeviculatum, and C. Stonei, are rooting freely, and may, if necessary, be repotted. Specimens requiring increased rooting space should be turned out from their receptacles and the old drainage materials removed from between the roots, disentangling the latter as much as possible, but taking care not to break or damage them. Select

a pot large enough to accommodate the plant for two seasons. Plants of the Sepentepodium section, such as C. quadrifide, C. Sedoni, and C. macrophyllum, that need re-potting, may be dealt with in a similar manner.

PLEIONE.—As plants of P. lagenaria, P. concolor, P. proteoxia, and P. Wallichiana pass out of flower they should be repotted, and this is best done when new roots are developing from the bases of the young shoots. Ordinary shallow Orchid pans without side-holes are the most suitable receptacles for these plants. The old compost should be shaken from the roots, and all dead portions of the latter cut away. About one dozen of the pseudo-bulbs may be planted together in a 6 inch pan, or the old plants may be broken up and the finest pseudo-bulbs selected and potted together. The smaller specimens that are not likely to bloom soon may be grown on for another season. The potting compost should consist of fibrous loam, chopped Osmundifibre, and Sphagnum-moss, in equal parts, mixing a quantity of broken crocks and coarse silver sand with these materials. The pans should be filled one-third their depth with clean crocks for drainage, covering the drainage with a layer of Sphagnum moss and a little of the compost. Place the pseudo-bulbs evenly over the surface, leaving sufficient space between each plant for a season's development. After being repotted the plants should receive little or no water for several weeks, and afterwards only sufficient to keep the compost moist. When in full growth afford the plants copious supplies of water. A light, airy position in the intermediate house is the most suitable place to grow these Orchids, and they need plenty of sunlight. Pleione humilis and P. Hookeriana have finished their season of active growth; the plants should be suspended in a cool house, and given only sufficient water to keep the soil moist. The rare P. yunnanensis should receive similar treatment.

THE FLOWER GARDEN.

By W. J. GUISE, Gardener to Mrs. DEMETER, Keele Hall, Staffordshire.

WALL PLANTS AND CLIMBERS.—In removing old and exhausted shrubs from wall plants and climbers leave sufficient young growths to fill the vacant spaces. Make large branches secure against winds. Tender plants need protection from severe frosts, such as is afforded by inserting bracken or dry litter between the branches. Heather and shoots of Yew may be employed for the same purpose.

EARLY-FLOWERING GLADIOLI.—If corns of early Gladioli are not already planted they should be set forthwith. Varieties of the Colville section planted in pots or boxes may be forced gently in flower by May, but care must be exercised, as very little fire-heat is necessary, and only when the plants are throwing up their flower spikes. To obtain a succession of blooms plant corns on a well drained, sunny border; if the soil is of a retentive nature, incorporate a quantity of old potting soil, or sand and leaf-mould with it. Plant the corns 4 inches deep, and cover the surface to a depth of 2 or 3 inches with decayed leaves as a protection from severe weather. It is a good plan to place spare lights over such sorts as the Bride, Peach Blossom, Salmon Queen, and others of the more delicate shades, directly they commence to bloom, to prevent the flowers being soiled in showery weather.

SPIRAEA ARGUTA.—The shrubby Spiraeas are excellent plants for the margins of lakes and streams. One of the earliest to bloom is S. arguta, the branches of which are completely covered during April with compact clusters of pure white flowers. Spiraeas thrive in most soils, and are quite hardy, but the early flowering varieties do best in a sheltered position, as the flowers are easily injured by cutting winds.

CARNATIONS.—Border Carnations which are being wintered in frames must have plenty of ventilation during mild weather. Keep the foliage as dry as possible; frost will not harm the plants, but a close, damp atmosphere would be very injurious. Young plants in beds should be examined after frosts, and pressed firmly into the soil if they have become loose.

EDITORIAL NOTICE.

Editors and Publisher.—Our correspondents would oblige by delaying in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors only intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 40.5.

ACTUAL TEMPERATURE.

Gardeners' Chronicle office, 11, Wellington Street, Covent Garden, London, Thursday, December 6, 1917. Bar., 29.9; temp. 32.5. Weather—Bright sunshine.

SALE FOR THE ENSUING WEEK.

WEDNESDAY—

Bulls at 67 and 68, Cleapside, at 3 o'clock, by Frotheroe & Morris.

The discovery of a large number of species of Rhododendron in China by French missionaries, and by Dr. Henry Wilson, Forrest, and others, has increased the interest and importance of the genus, botanically as well as horticulturally. Many of these species are now in cultivation in British and Irish gardens, and, although still on trial with respect to hardiness and attractiveness, enough is known about them to satisfy gardeners that they are worth growing. Owing to the wide distribution of many and their consequent variation, probably also to their crossing readily with each other, the naming of the new Rhododendrons is difficult. Certainly too many species have been made, and this matter will have to be righted when more is known about the plants. Meanwhile, both amateur gardeners and nurserymen are forming collections of them, and in those parts of the country where the conditions are favourable to Rhododendrons the collections are rapidly becoming of great interest.

Wilson has stated that the centre of the greatest concentration of the genus is the wild and rugged region of the China-Tibet borderland, a continuation of the Himalayas. Consequently, the Sikkim-Himalayan species and those found in China show a close family resemblance. We owe a great deal to the Sikkim set, which Sir Joseph Hooker introduced and helped to popularise as garden shrubs about three-quarters of a century ago. Plant breeders were at first slow to turn some of the best species to account, *R. arboreum* and *R. campanulatum* being the only two that were much used, in combination

with the older caucasicum × catawbiense race. The best work had been done with *Azalea indica*, and the Swamp Honeysuckles, and we are not likely to get anything out of the new comers to beat these two races. But we do know now how to mate, how to breed plants, and almost every gardener tries his luck at crossing plants of some kind. For this reason the acquisition of such a wealth of fresh material as is provided by the Chinese Rhododendrons makes an epoch in British gardening. There will be no difficulty in growing them, nor in breeding from them, and before long we shall have them as generally in favour as Roses are at the present. Indeed, it may be said of Rhododendrons now that they are by far the best of all hardy shrubs.

Comparatively little has been written about Rhododendrons as garden plants. Sir Joseph Hooker published several interesting essays, which helped gardeners to some extent, and his big book, *The Rhododendrons of Sikkim-Himalaya*, revealed their beauty. One of the first to become enthusiastic about them was the late J. H. Mangles. He got together a collection of the species in his garden at Haslemere, where he made many crosses that had not been made before. He was generous with his plants, and it is more than likely that good hybrids which appeared in other gardens owed their origin to his skill. He contributed inspiring articles on Rhododendrons to the *Gardeners' Chronicle*, rousing an interest in the plants which has since spread with good results.

The first book about them was the excellent 1s. 6d. treatise, by Mr. William Watson, which is one of the *Present-Day Gardening* series, and was published about five years ago. Now another book many times larger than, and a hundred times the price of, that little effort, has been furnished by Mr. J. G. Millais, an amateur fancier, the author of a fine illustrated work on *The Mammals of Great Britain and Ireland*, and of other books of the *Edition de Luxe* kind. In dealing with Rhododendrons, Mr. Millais has been assisted by other amateurs, including Sir Edmund Loder, Mr. John Williams, and Mr. Percy D. Williams, whilst Mr. Hutchinson, of Kew, has helped with the botany of the subject. Mr. Millais tells us that he has visited all the best gardens where Rhododendrons are grown, and that for some years he has had a collection of his own at Compton's Brow, Sussex. The illustrations, which are numerous, some coloured, some collotype, others reproductions of photographs, have been made from cultivated plants. They are on the whole good, some particularly good, a few not good enough. It was a big undertaking for a comparative beginner in the fancy, but Mr. Millais has got through with it very creditably. The book is not intended for professional men, but for wealthy amateurs who like large volumes (it is larger than the old-fashioned family Bible) and who want to know something about Rhododendrons as garden plants. The

chapters are on Gardens Generally; Distribution; Chinese Species; Hybrids; Cultivation; Gardens where Rhododendrons are a Special Feature; Description of Cultivated Species, Hybrids, and Varieties, with notes on their Habits in Gardens. The last chapter is by far the most valuable. Many of the species that are included are as yet scarcely known, but they are all supposed to be represented by living plants in British collections.

A reviewer is expected to point out faults as well as good qualities, and there are some in Mr. Millais' book. Mistakes in spelling are too frequent; there should be none in a book of this character. The use of italics and of initial capitals is inconsistent, and, in some places, really irritating. Carelessness in the collation of descriptive and historical information is also in evidence, as, for example, *R. Batemannii* is given as a variety of *R. arboreum*, a hybrid between *R. campanulatum* and *R. arboreum*, and as a distinct species. It was scarcely worth while to give lists of supposed crosses which have not yet flowered. Every breeder knows that this is counting the chickens before the eggs are hatched. The big trade collections of Rhododendrons appear to have been overlooked in the text. The nurseries of the Waterers, John and Anthony, have done much for the Rhododendron cult, and their collections to-day are unrivalled. Nor, for that matter, has Kew received as much credit as she is entitled to. Hooker's work was really Kew work, and the collections there now are a great national asset.

These criticisms are by the way. Mr. Millais has done a great service to horticulture by collecting this big bookful of information about and pictures of Rhododendrons. He would add to it not a little by publishing the work as a small volume at about 10s., giving all the letterpress and a few of the illustrations.

A LINNEAN SOCIETY FOR SWEDEN.—At the meeting of the Linnean Society, held on the 29th ult., the secretary stated that a new Linnean Society had been recently established in Sweden as "Svenska Linné-Sällskapet," intended as a means for spreading information about Sweden's greatest naturalist, CARL VON LINNÉ (1707-78). It proposes to do this by the publication of works by LINNÉ and his pupils; by throwing new light from modern standpoints on LINNÉ'S personality; by drawing up a catalogue of all known memorials; and by founding a complete Linnean library. The president is Dr. TYCHO TRILLBERG, a lineal descendant of LINNÉ.

FRUIT FOR THE RED CROSS.—On p. 211 we gave some particulars of a sale of Apples at Liverpool arranged by Messrs. KER, LTD., in aid of the Red Cross funds. On the 29th ult. another display in 80 dishes was made by the same firm, which, being ruffed for, realised £101 10s. On this occasion, 5 per cent. of the takings will be given to the gardening charities.

SCOTTISH NATIONAL UNION OF ALLOTMENT HOLDERS.—A conference is to be held in Dowell's Rooms, 18, George Street, Edinburgh, on December 15, at 4 p.m., for the establishment of a Scottish National Union of Allotment-holders.

* *Rhododendrons and their Various Habits.* By J. G. Millais. Price 3s. 6d. (Longmans, Green & Co.)

It has been estimated that there are 30,000 allotment-holders in Scotland, of whom about 5,000 are in Glasgow, and some 3,000 in Edinburgh.

NORTH AMERICAN POTATO CROP.—It is estimated that the Potato crop in U.S.A. is 100,000,000 bushels in excess of last year, but in spite of the large surplus prices rule as high as 2 dollars a bushel.

WELSH SMALL-HOLDING COLONY.—It is reported that the Board of Agriculture has completed the purchase of 1,400 acres at Pembrey, in Carmarthenshire, for a small-holding colony for discharged Welsh soldiers and sailors. The Board will take possession next Michaelmas, and the land will be tamed into market gardens.

PRISONERS OF WAR.—The total number of prisoners of war working in agriculture is now 5,065. Schemes for the employment of a further 1,500 men are about to be started.

ALLOTMENTS AT BERMONDEY.—A remarkable quantity of good vegetable produce has been obtained during the year from the allotment grounds cultivated under the direction of the Gardens and Open Spaces Committee of the Bermondsey Borough Council. The district is one of the most thickly populated in London, and the ground available was of the most unfavourable character, which makes the results all the more creditable. A special letter of appreciation was sent to the superintendent, Mr. W. H. JASANT, from the Director of Horticulture, Board of Agriculture and Fisheries, for the valuable work done under his direction.

LOCAL SOCIETIES.—The annual meeting of the Garden City Horticultural Society was held in the Howard Hall, Leythorpe, on Monday, the president Mr. W. H. GAVIN in the chair. Mrs. GAVIN presented the prizes for the Potato-growing competition, and Messrs. HAYDON and HERRINGTON gave an excellent report of the school gardens. Mr. C. F. BARR was elected president for the coming year. The accounts presented at the annual general meeting on Thursday of the Croydon Horticultural Society showed a credit balance of £25 10s., which was handed to the Mayor of Croydon War Fund. The Mayor, Alderman HOWARD BOURNE occupied the chair, and was re-elected president of the Society, and Mr. L. R. WYSHAM as secretary.

INCREASES IN PRINTERS' WAGES. The Federation of Unions in the printing and allied trades, comprising fourteen in all, has recently put forward demands for an increase of wages of 6s. per week for every man, the conversion of the present war bonus of 7s. per week into wages, and payment for all public holidays. The matter has been compromised by the concession of an advance of 4s. per week, payable from November 2, 1917, and a further advance of 2s. from January 3, 1918. The second and third claims have been shelved for the present. These and other concessions since May last add to the already high prices of printing another 25 per cent. increase.

AGRICULTURAL MACHINERY FOR SPAIN.

The *Board of Trade Journal* informs us that H. M. Consul has recently received a letter from a British subject, who is the manager of a joint stock company in Malaga dealing in agricultural implements. The writer points out that to expect Spanish firms to purchase a large number of agricultural implements, and at the same time to require payment on a cash basis, is a British pity, render business out of the question. Manufacturers of agricultural implements in the United Kingdom who are desirous of exporting their goods should, whenever there is an opportunity for so doing, form an Association and appoint agents or representatives in Malaga, to travel the agricultural districts and study the customs and requirements of the Andalusian and North African farmers. Extensive propaganda would be productive in a short while of the best results to the manufacturers. The writer states

that unless the hand implements above referred to are of the required form they would be useless in the Andalusia district. The question of the supply of agricultural machinery and implements suitable for Andalusian soil is a complicated one, and he instances the case of hand implements used in ordinary every day work in the field or garden, which require special attention. This is due to the peculiar angle at which the Spanish agriculturist holds his head when working, for Spaniards in Andalusia work in a stooping position instead of in the nearly upright position preferred by labourers in most countries. H. M. Consul at Malaga also states that a commission agent in Granada desires to obtain agencies for United Kingdom manufacturers of agricultural

A WELSH CONSERVING DEPOT.—A movement is on foot in the Llandudno district for the better organisation of the fruit and vegetable supply of the surrounding area. An enormous quantity of fruit and vegetables, fresh or preserved, is imported to Llandudno, Colwyn Bay, and other coast towns of South Wales in the holiday season, from outside sources. On the other hand, many tons of fruit and vegetables grown in the district are said to be wasted in every year of good crops from sheer lack of local organisation. A conference is being held this week end at Llandudno Junction with a view to the creation there of a Horticultural Depot. It seems likely that this depot will be run on co-operative lines, and that canning, drying, and

(Drawn by Miss Frances Bungard.)

FIG. 33. RED CURRANT (CONDICION 1/2 NAT. SIZE).

(See p. 232.)

machinery and chemical products. This province is mostly agricultural, and up to quite lately agricultural machinery was very rarely employed. There is no doubt that British firms have at the present time an opportunity of developing business in the Granada district. Further in this connection, H. M. Consul has collected and forwarded to the Department of Commercial Intelligence a number of catalogues of agricultural machinery, etc. Most of these catalogues do not appear specially adapted to Andalusia, but they show how non-British firms are working. The catalogues may be consulted by British manufacturers of agricultural machinery and implements at the Department of Commercial Intelligence, 73, Basinghall Street, London, E.C. 2.

pulping will be undertaken, in combination with the handling of fresh fruit and vegetables. Llandudno Junction is a good centre for dealing with the produce of Anglesey, Carmaronshire, and parts of Merionethshire. It need hardly be said that local efforts of this sort have the warmest sympathy of the Food Production Department and the Ministry of Food. Their general adoption throughout the country would go far to solve many of the minor problems of food production and distribution.

EFFECTS OF SUNLIGHT ON CROPS.—At the Royal Society, on November 20, Colonel H. E. RAWSON, C.B., read a paper before the Fellows of the Royal Colonial Institute on "The

sun as Empire builder. The lantern there is fitted with an epidiascope, and enabled him to show a specially interesting collection of "sports," which are said to have been produced at will by his system of selective screening. This consists of placing a plant in such a position that it will only get full sun on it at selected periods of daylight, and will be in the shade of distant trees, a house, or a wall at other times; or if it is growing in a conservatory, will be screened by a post or a shelf, or perhaps a strong blind at such times. He has found that the amount of red and blue light falling on the plant varies greatly with the sun's altitude, and that screening affects their saturation. By taking advantage of this the well-known "sports" of *spinifloria*, pro-

A REVISION OF THE RED CURRANTS.

(Continued from page 217.)

GONDOUN GROUP.

This very distinct group contains the descendants of *R. petraeum*. The stout wood, long buds, red campanulate flowers, and the stout coriaceous leaves all render them easily distinguishable.

GONDOUN (see fig. 38). Syn. *Bridgeford Red*.—*Flowers*.—Closely resembling *R. petraeum*, buds crimson, flowers campanulate, dark claret-red, sepals overlapping, not ciliated, petals broadly wedge shaped, rachis very hairy.

Leaves.—Young growth red, adult blackish-green, very thick and bullate, stiffly held upright.

Fruit.—Bunch medium size, berries large and even, very bright clear red, a little flattened, rachis downy.

Season.—Late.

Buds.—Large, long and flat, pressed close to wood, almost exactly resembling *Prince Albert*, and indistinguishable in this state.

Growth.—Very vigorous, stout, upright shoots.

Origin.—Raised by M. Gondoun at St. Cloud and described by Janczewski as *R. Gondoun*, a hybrid between *petraeum* and *vulgare*. It very closely resembles *Prince Albert*, but can be distinguished by the more hairy rachis and the much thicker and darker leaves and darker colour of the flowers. Like all this group it retains its leaves late in the autumn.

PRINCE ALBERT SYNS. *Rivers' Late Red*, *German Soure*, *Knights* and *Hollandische Rote* (on the Continent), *Ruhm Von Harlem*, *Verrieres Rouge*.—*Flowers*.—Almost exactly the same as in *R. petraeum*, buds very dark crimson-red, flowers campanulate, red, sepals overlapping, ciliated, petals very broad wedge, rachis hairy.

Leaves.—Young state strongly red-tinged as are the young shoots, adult very dark green, fairly thick, and very stiffly held upright.

Fruit.—Bunch medium size, berries large, even, bright red, a little flattened, slumping, rachis downy.

Season.—Late.

Buds.—Long and flat, dark brown, a little hairy, clinging close to the wood, the leaf scar light brown and very prominent.

Growth.—Very stout, vigorous, and upright.

Origin.—This variety has been grown for some 200 years or longer. It is the *R. pallidum* of Otto and Dietrich, and considered by Janczewski to be a hybrid of *petraeum* and *vulgare*.

GOEGGINGERS PYRIFORM—This curious form has Pear-shaped fruit, and there is also a white variety. In foliage and other characters it is like *Gondoun*, and a true *petraeum* derivative.

Raised by Heinrich Goegginger, a market gardener in Riga, and first described by Dr. Regel in 1878.

SEEDLESS RED, *Kornlose*.—This curious variety is also a form of *Gondoun*, alike in all respects save its dwarfier habit. The seeds do not set, and there are thus only the soft, unfertilised ovules in the berry. So far as I have tried it its great fault is that the berries are

very apt to run off, and if this habit is maintained it will be valueless for garden uses. Found by Herr Petzold in Hessen.

THE SCOTCH GROUP.

This group contains those varieties which show their descent from *R. rubrum*. They have in common the bell-shaped flower, more or less tinged with red, the habit of holding out the flowers at right angles to the stem, the stiff, wiry rachis and the stiff, upward-folding foliage. It is somewhat difficult to pick out the distinctions between some of them, as they are nearly identical in many cases. One of the oldest of this type is doubtless the *Chiswick*, but as it is now so little grown I have adopted the *Scotch* as the type, as this form is very largely grown for market purposes around London, and will therefore be known to a large number of people.

SCOTCH. Syns. *Millern Red*, *London Market*, *Fowler's London Red*.—*Flowers*.—Urecolate, green, striped with red, buds faintly red, sepals overlap, petals wedge shaped, rachis a little hairy, stiffly held upwards.

Leaves.—In young state green, late in opening, adult, pale green, rather small, strongly up folded, holding on late in the autumn.

Fruit.—Bunch medium length, compact, berries held firmly to one side, rachis stout, hairy.

Season.—Early.

Buds.—Winter state, moderately large, dark brown, very slightly hairy, rather away from wood.

Growth.—Very sturdy and rather upright.

Origin.—Undiscovered.

This Currant is very largely grown for market purposes and is remarkably prolific and of bright colour.

LA CONSTANTE.—*Flowers*.—Slightly urecolate with slight ring, sepals slightly brown-tinged, petals broad wedge shaped, bunch held stiffly outwards, rachis with dense curling hairs, which distinguish it from *Scotch*. Very late in opening.

Leaves.—Young state green, adult very dark green, upward folded, stiffly held.

Fruit.—Bunch moderately long, stem (before fruits begin), $\frac{1}{2}$ inch, berries bright red, held to one side, rachis turns yellow when fruit is ripe.

Season.—Very late.

Growth.—Vigorous and very upright.

Origin.—Undiscovered. Though very like *Moore's Ruby* it is distinct in many characters, and is one of the latest and best of the Red Currants.

MOORE'S RUBY.—This resembles *Scotch* very closely in all characters, but the foliage is of a darker and slightly glaucous green, and the fruit ripens late, bunch a little longer. Hardly distinguishable in winter state.

CHISWICK RED.—*Flowers*.—Urecolate, yellowish-green, sepals hardly meeting, turned back, petals markedly wedge shaped, rachis downy.

Leaves.—In young state slight yellow, brown tinge, adult exactly resembling *Scotch*, except that the silver edge is rather more pronounced.

Fruit.—Bunch longer than *Scotch*, berries on stiff, wiry stems held to one side.

Buds.—Fairly large, outward held, slightly hairy.

Season.—Early.

Growth.—Vigorous and sturdy, upright.

Origin.—Undiscovered. This seems to agree with the *Chiswick* as described by Thompson and Barron, but it is apparently now almost out of commerce, as I received it from one nursery only.

(To be concluded.)

THE ACORN CROP.—The Food Production Department of the Board of Agriculture urges that in places where Acorns are still lying on the ground, collecting parties should be organised without delay. A leaflet on the Feeding of Acorns may be obtained post free from the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, S.W. 1.

(Drawn by Miss Frances Bunnard.)
FIG. 39.—RED CURRANT "SCOTCH" ($\frac{1}{2}$ NAT. SIZE.)

liberation, fasciation, and leaf division have been produced several years in succession, and some of them have been fixed in the case of *Nasturtium*. Eight flowers have grown where one grew before, and ten cords have bifurcated where there was a single stem before. According to the author of the paper, the effect of a shadow on a fruit tree should be noted, for the scent of flowers varies with the selective screening and the flavour of fruit should vary also. The colour of the light found on a fruit tree growing in grass land is not the same as when in cultivated soil. Speaking generally, pruning fruit trees increases red light and diminishes blue, while increased illumination through leaves excites a different response from the plant from that where there are no leaves. The experiments are quite in their infancy, but the results already obtained are interesting.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

PLANTING RHODOENDRONS.—Your correspondent, p. 212, states that better results are obtained from mid April planting than autumn planting. I have my doubts about this, except in the case of garden hybrids, as many of the Himalayan species and hybrids are then in bloom, or about to bloom. I do not say that planting at that date is never successful, for I have practised it myself in a suitable season, and when I was obliged to do so; but I have planted in the winter for many years, and have handled thousands of these plants. Himalayan species and garden hybrids. Regarding soils, any soil that will grow Bracken and Heather is suitable for Rhododendrons. The ground is well broken up to a depth of 2 feet 6 inches, and plenty of good cow manure incorporated. An important point is to plant fairly thickly, so that the plants will partly shade each other's roots. Then, after two or three years, the bed should be re-made or the plants thinned. The addition of some more manure, and after this mulching, will be sufficient for many years. *R. praecox* is showing colour now, and with open weather should soon unfold its flowers. At the present time all seed-pods will probably be ready to gather, especially those of the earlier-flowering hybrids and species, such as *R. praecox*, *R. Thomsoni*, and *R. ciliatum*. The seed collected will be carefully labelled and stored in a dry place until the end of February, when it will be sown in shallow boxes or seed pans in a temperature of about 55° or 60° F. *F. Cook.*

THE EFFECT OF ONE PLANT ON ANOTHER.—Although I do not assert that it is an example of the effect of a toxic excretion, I think that the following observation is of interest. After three years, during which they had yielded fairly good crops, had been manured lightly, and mulched, four or five rows of Strawberries were dug up and the ground dug and planted with spring Cabbage. The rows of Cabbage occupied not only the Strawberry quarter but ground on one side of it as well. Within a week of planting a remarkable difference was to be observed between the Cabbage plants planted on the old Strawberry quarter and that planted beyond its limits. The latter thrive and make good growth, and left the former behind. Now a matter of 6 weeks after the planting the Cabbages on the ground from which the Strawberries were lifted are still puny, and have a starved look. Toxic or no toxin, it is hard to believe that their miserable growth is to be ascribed to poverty of soil, for the Strawberries did not show any lack of vigour. *L. N.*

MR. GEORGE CASBELL.—Readers of the *Gardeners' Chronicle* will remember Mr. George Casbell, who, for nearly twenty years, filled the position of Garden Superintendent at the Crystal Palace. Every exhibitor who attended the shows held at the Palace will know how ready he always was to give any assistance in his power to those in the slightest difficulty. Owing to a serious illness, together with changes at the Crystal Palace, Mr. Casbell was forced to relinquish his charge. For nearly three years he has been under the doctor and has had a nurse in the house. At the present time he is in bed for twenty-one out of each twenty-four hours. It is scarcely any wonder that the savings he had put by have vanished. He has only £20 per annum he receives from the Gardeners' Royal Benevolent Institution, 5s. per week from his club, and occasional help from his son, who is a private in the Army. As treasurer and secretary of the National Chrysanthemum Society, we feel certain that there are many who would wish to render him some practical assistance in his time of need. Let us say, therefore, that any help readers may be disposed to give should be forwarded immediately to Mr. Curtis, 35, Wellington Street, Covent Garden, W.C. 2. *John Green, Richard J. Witty, Charles H. Curtis.*

GARDEN ALLOTMENTS AT CHESTER.—A census taken in June last revealed the fact that there were 1452 acres of land under cultivation in the neighbourhood of Chester, representing 1,229 allotments, 153 of which are under the

control of the Chester Corporation, the remainder being under the control of the Hodge Urban Council and other public bodies in the neighbourhood, as well as private owners, including the Duke of Westminster. The Chester Paxton Society, that for a long series of years has done much educational work in various branches of gardening, has dealt with the allotment question in a very practical way. It was felt by that body that as the majority of these new allotment tenants would be novices at gardening, a short treatise giving cultural hints, and naming some of the best varieties of vegetable to cultivate in the neighbourhood should be issued. The treatise was written by Mr. N. F. Barnes, and copies of the work were supplied free of charge to the allotment holders in March. The Society further offered a series of prizes amounting to £15. In addition to cultural certificates for the best and heaviest cropped allotments, (A) The best kept and heaviest cropped allotment which has been cultivated for two or more years, for the purpose of providing a food supply in war time. (B) The best kept and heaviest cropped allotment on land cultivated for this purpose for the first time. (C) The best kept and heaviest cropped cottage garden for the purpose of providing a supply of food in war time. Over a hundred entries were received for these prizes. Reported visits were made by the winners appointed to make the awards, and the results were made known in August. By request of the Board of Agriculture the honorary secretary undertook to act as its local representative, and in consultation with the executive of the Paxton Society it was decided for working arrangements to group these 1,200 odd allotments into six colonies. To assist the beginners, twelve practical men belonging to the Society were then appointed to act as honorary advisers to these colonies, and the services rendered by these practical men have gone a long way towards bringing the movement to its present high standard of efficiency. Not an instance is known of any holder wishing to give up his allotment, on many of them are quite prepared to take long leases of the plots they are now cultivating. The area of these plots varies a little, but the average holding represents 500 square yards. Potato culture enters largely into the cropping of these allotments. Peas, Beans, Cabbages, Cauliflowers, and a succession of other vegetables were also cultivated. One example will suffice. A piece of land 4½ acres in extent, which was bought some few years ago for building purposes, but not utilised, was, until this spring, lying idle. This is now occupied by 60 allotment holders, and the owner's rental has in consequence risen from an average of 50s. per annum to £26 10s. per annum. Another interesting case illustrating intensive culture was recently noted where a piece of grass-land close to the goods yard of a railway station in the suburbs was given over to a few platelayers. This was divided into six plots, about one eighth of an acre each, at a nominal rental of 2s. per plot. On one of these the holder sold off his plot last year 4 cwt. of Onions, at prices ranging from 3d. to 4½d. per lb. This by no means represented all his produce, as in addition he sold other vegetables amounting to over £20, and in addition he was able to supply the wants of a moderately large family with a plentiful supply of Potatoes and other vegetables for the whole of the year. *G. D. Miles.*

DUGOUTS IN THE GARDEN.—If foreign government treaties are to be mere "strapped paper" in the future, the possibilities of garden dugouts are worthy of every consideration. Miniature tunnels can be bored on hillside positions in such a way that the entrances are disguised, or, at any rate, that they are inconspicuous, so as not to mar the beauty of a garden. The following are some of the most important uses of a dugout: (1) As a comparatively safe retreat from "rain clouds." (2) It may be used as a summer house or shelter from inclement weather. (3) The interior might serve as a motor garage or a photographic "dark room." (4) An exterior slope of the ground would be advantageous as a starting place for an aeroplane. (5) A suitable place for the storage of Apples, Pears, tuberoses, roots, and vegetables. (6) It should prove useful for the cultivation of Mush-

rooms, Sea-kale, Rhubarb, blanched Chicory, white Lilac, Lilies of the Valley, etc. The dugout could be heated, if required. (7) If sufficient light could be afforded the place would be suitable for wintering large Palms in tubs, Tree Ferns, standard Bays, and large specimen Fuchsias. These could be placed out on terraces during the summer months. On the Cotswolds, Apples and Pears are already stored in dugouts, the interiors of such places being sometimes lined with dry Gorse or Bracken. Bashes might also prove suitable. This is a matter of importance when we read that tons of fruit are spoilt for lack of marketing baskets! Why not store the fruit, in ideal conditions, in tunnelled dugouts? Where large quantities of clay are excavated it could be made into bricks, tiles, drainage pipes, and flowerpots. Burnt ballast is also useful for many purposes. Fertile soil should never be deeply buried or otherwise wasted. It is more useful at the surface for purposes of cultivation. Where there are large areas of infertile soil this might be surfaced with dredgings from the rivers, waterways, and canals. *Frank James, Mitchell.*

SOCIETIES.

ROYAL HORTICULTURAL.

DECEMBER 4.—The meeting held in the Drill Hall on Tuesday last completed the list of fixtures for the year.

Novelties were submitted to the Floral Committee, and Awards of Merit were won by two new Carnations. The only other awards in this section were a Silver Flora and a Silver Bank San Medal, both awarded to groups of Perpetual-flowering Carnations, staged by Messrs. ALWOOD BROS. and SEVANT LOW AND CO. respectively.

There were several attractive groups of Orchids, and a number of novelties, for which three Awards of Merit were given.

The Fruit and Vegetable Committee made no award to a novelty, but awarded three medals for collections. Apart from the floral exhibits, there were several of a miscellaneous nature, including a collection of artificial manures staged by Messrs. LARG AND SONS, Hounslow.

Floral Committee.

President: Messrs. H. B. May (chairman), W. J. Bean, J. Green, J. F. McLeod, C. R. Fieldler, F. Page Roberts, T. Stevenson, W. Howe, J. Jennings, W. P. Thomson, J. Heal, C. Dixon, J. Dickson, A. Turner, W. H. Morter, C. E. Pearson, E. H. Jenkins, E. A. Bowles, R. C. Noddy, E. F. Hazelton, A. G. Jackson, and R. Hooper Pearson.

Awards of Merit.

Carnation Mrs. Edward Dooty.—A pale yellow, ground fawn variety of the Perpetual-flowering type, the petals irregularly striped with vermillion. The bloom is of large size, and possesses a long, stout stalk and firm calyx. Shown by Messrs. ALWOOD BROS.

Carnation Mrs. Edward Dooty.—The colour of this novelty is exactly similar to that of *Carola*, but the petals are not of such firm substance. Pot specimens of the flower were exhibited, showing that the plant is of good habit and robust growth. Shown by Messrs. SEVANT LOW AND CO.

Orchid Committee.

President: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), William Bolton, Walter Cobb, E. R. Ashton, Arthur Dye, R. Freeman White, Frederick J. Hambury, Pamtia Rath, C. H. Curtis, T. Armstrong, W. H. Hatcher, S. W. Flory, R. A. Rolfe, J. Charlesworth, J. E. Shill, and Fred K. Sander.

Awards of Merit.

Sophia Cottley's Favourite (C. Fabia × S. C. Davis).—Shown by Mr. J. E. SULL, The Dell Gardens, Enghfield Green. The flower is nearly as large as that of *C. Fabia*, and the sepals and petals are pale yellow. The lip is rose-coloured, with a reddish purple tinge and darker veining

over the front lobe, which has a narrow cream-coloured margin and gold lines extending from the base to the centre.

Cypripedium insipide var. Louis Stander, from Messrs. SANDERS, St. Albans.—A fine, imported variety of large size and good form. The broad dorsal sepal is white above and yellowish-green on the basal half, dark reddish-brown blotches extending from the base, changing to purple in the white area. The lip and petals are coloured as in the type, but they are of broader proportions.

GROUPS

Dr. MIGUEL LACROZE, Bryndur, Rochampton, showed Sophro-Laelio-Cattleya Marathon, Bryndur variety, with deep rose-naive flowers, the sepals having white midribs at the base, and the petals tinged with crimson up the middle; the lip is ruby-crimson with thin gold lines in the base; also Laelio-Cattleya Serbia var. Opal, a grand flower with white sepals and petals and rich claret-purple coloured front to the lip.

MESSRS. ARMSTRONG AND BROWN, Orchid-hunters, Tambridge Wells, were awarded the Williams' Gold Medal for a group, in which about forty plants of their famous white-petalled strain of Cattleya Magge Raphael alba were a feature, two of the best varieties being Dreadnought and splendens. Good novelties were shown in Laelio-Cattleya Diana var. Buttercup (L. C. Jacobus × L. C. Ophir), a distinct hybrid with a showy flower having yellow sepals and petals, the lip and short side lobes veined with purple and reddish rose front lobe; *Cypripedium Arthurianum nobilior* (insigne Harsfield Hall × Fabricianum), with a finely blotched dorsal sepal; and *Odontoglossum* hybrids flowering for the first time.

MESSRS. CHARLESWORTH AND Co., Haywards Heath, were awarded a Silver Banksian Medal for a group which included finely-flowered *Odontoglossum* at the back, fronted by Cattleyas and Laelio-Cattleyas, the best of the latter being the new L. C. Seleste (L. C. Fascinator × C. Trianae), a large white flower, slightly tinged with rose, and broad purple lip with yellow disc. A novelty among the *Odontoglossums* was *O. xanthinum* (ardentissimum xanthos × luteo purpureum Vuytstekeanum), with white ground colour blotched with light yellow.

MESSRS. SANDERS, St. Albans, were awarded a Silver Banksian Medal for a group of *Cypripedium* of excellent quality, among which we noted *C. Hippolyta* (Dante × Hera Enryades), a new form of good size and shape, and Cattleya Magge Raphael albo-cornea, clear white with violet-coloured front to the lip.

MESSRS. E. H. DAVIDSON AND Co., Orchid Dene, Twyford, showed Sophro-Laelio-Cattleya L. McKenna (S. L. C. Odipus × C. Dowiana aurea), a dark claret-coloured flower; and Sophro-Cattleya Dorcas (S. C. Dora × C. Dowiana aurea), yellow, with rose lip veined with orange at the base.

MESSRS. STUART LOW AND Co., Jarvisbrook, Sussex, staged a selection of hybrid Orchids, including good Sophro-Cattleya Doris, S. C. Pearl; Laelio-Cattleya Alex, and Cattleya Alci-melia alba.

Fruit and Vegetable Committee.

President: W. Poupert (in the chair), and W. Wilks, E. W. Roach, J. Harrison, A. W. Metcalfe, A. Ballock, J. G. Weston, W. H. DIVERS, E. Beckett, Owen Thomas, W. Bates, and F. Jordan.

Colonel W. N. DAVIS, Salt Hill House, Slough (for Mr. W. R. Ballock), was awarded a Silver Knightian Medal for a collection of Apples and Pears. This was a fine exhibit; the fruits were model specimens in every respect. Fruits of Apple Court Pendl Plat were of a remarkably high colour, and the same remark applies to Adams's Pearmain, Christmas Pearmain, Winter Collin, Cox's Orange Pippin, and Blenheim Pippin. American Mother and Blenheim Pippin were the best and most richly coloured fruits, being far above the average.

Sir DANIEL GOUGH, Highlands, Chelmsford, showed a collection of Apples, for which a Silver Banksian Medal was awarded.

Mrs. MUIR, Marlow-on-Thames, showed "Mowden" preserves, for which a Silver Banksian Medal was awarded.

PERPETUAL-FLOWERING CARNATION.

DECEMBER 4.—The annual meeting of this Society was held on the 4th inst. at the offices of the British Wholesale Florists' Federation, Wellington Street, Covent Garden. Mr. J. S. Branton presided. War conditions have limited the operations of the Society and restricted its income. One show was held in December, 1916, and the Society published a Year-book in 1917. The membership stands at 197, and on a turnover of £134 3s. 6d. there is a balance in hand of £26 8s. 4d., as compared with the balance of £46 3s. brought forward from 1916. There was no lack of enthusiasm on the part of the members present, and they re-elected the whole of the officers, added Mr. T. Stevenson and Mr. Pinches to the committee to fill vacancies, and agreed that a Year-book should be published next year but no exhibition be held. The name of the Society was altered. Originally the Winter-Flowering Carnation Society, it became the Perpetual-Flowering Carnation Society, and in future is to be known as the British Carnation Society. Efforts to amalgamate with the National Carnation Society have not materialised, and the new title has been adopted so that new types of Carnations may receive consideration and the scope of the Society be widened. Mr. T. A. Weston was voted an honorarium of twelve guineas for his services as hon. secretary.

The Floral Committee met at the Drill Hall, in conjunction with the fortnightly meeting of the Royal Horticultural Society, on the 4th inst. and made the following awards:—

FIRST-CLASS CERTIFICATES.

Carnation Winter Glow.—A well formed bloom, possessing plenty of substance in the petals. The colour is glowing corse, of exceeding depth and brilliancy. Shown by Messrs. STUART LOW AND Co.

Carnation Marion Willson.—(See award by the R.H.S. Floral Committee.)

CROPS AND STOCK ON THE HOME FARM.

Pigs.

ALL who have the convenience to keep breeding sows should not fail to do so, as the short age of pigs in the country is a matter of some seriousness. In view of the prices obtained for pork, bacon, and stores, no one can say pig-keeping is not profitable. I do not say that with the present high price of feeding stuffs every out-thrower can fatten even one pig with a fair return for labour and outlay. We look more to dairy farmers, especially those who make butter, to rear and fatten pigs in quantity, as with an abundance of milk from the latter source small pigs thrive amazingly. The cost of keeping sows to the ordinary farmer is not an expensive matter if some provision is made for growing Cabbage, Maize, and Mangolds, for with the surplus small Potatoes but little else is required beyond a small quantity of bran twice daily. These are inexpensive foods, within the reach of every person who tries to produce them. Of the foods named, Cabbage produces an astounding quantity from quite a small area when good cultivation is practised. A further advantage to the pig keeper is a small meadow where the sows can roam, obtaining much food, and what is of considerable importance, exercise. All breeding animals require gentle exercise. Where a yard with a snug straw bed is available for night, and an outside room during the day, the conditions are favourable to success.

Sows in such conditions should produce fine litters of young within two years. From the right sort of pig it is reasonable to expect ten stores, sometimes more. Of late, good quality stores ten weeks old have made from 30s. to 40s. each, sometimes more.

In counties there are fashions in breeds of pigs, also the local requirements, of what the pork butcher and bacon factor require personally. I have a strong penchant for a cross between a Large Yorkshire White sow and a Middle White Yorkshire Boar or a Berkshire boar. From the former I obtain a larger number of pigs generally than from a Berkshire boar. Therefore, as numbers tell, I prefer the former. A Large

Sussex sow and a Berkshire Boar answer capitally; some reverse the sows and boars. No breed of pigs come to hand so quickly as pure-bred Berkshires alone, but the general fault in my experience is small litters of young. I allow the boar to run with the sows always, as exercise is conducive to health, even in the sire. The six pigs sows are separated from the rest only two or three weeks before the young are due. Naturally in the winter the sow occupies as warm a sty as is possible in reason, free from draught, and with a southern exposure, so that the newly-born pigs can have the advantage of sun, which they revel in. A close wood floor, with a gentle slope, is an advantage over brick, cement, or earth, being warmer, and naturally prevents to a great extent cramp in the young pigs, which is all too common on cement floors. After birth of the young the sows should be carefully and liberally fed with milk and meal. The young pigs, too, should be quickly encouraged to drink milk in a separate trough in an adjoining sty, where they are secure from the ravages of food by the sow, who seems to think all is for herself only. My plan is to have a temporary hole through the partition of one sty to the next, through which the small pigs quickly find their way. The more attention that is paid to the sow and her young in regard to food, warmth, and cleanliness, the quicker the growth assured. *E. H. Molyneux.*

AGRICULTURAL WAGES BOARD.

The Board of Agriculture and Fisheries, after consultation with the Ministry of Labour, has established an Agricultural Wages Board for England and Wales under the provisions of Part II. of the Corn Production Act, 1917. The Board, in accordance with the regulations made on November 8, consists of 39 members, of whom seven are appointed as impartial persons, and the remainder as representative of the interests of employers and workers respectively in equal numbers. Of the sixteen representatives of employers, the Royal Agricultural Society, the National Farmers' Union, the Central Chamber of Agriculture, and the Welsh Agricultural Council, were each invited to elect two members, and of the representatives of workers, the National Agricultural Labourers' and Rural Workers' Union were invited to elect six, and the Workers' Union two. The remaining representative members have been nominated by Mr. Prothero, after consultation, in regard to the representatives of workers, with Mr. G. H. Roberts.

ANSWERS TO CORRESPONDENTS.

ADDRESS: J. T. W. The address of the secretary of the London and Southern Counties section of the National Union of Allotment Holders is Mr. D. Chater, 8, Buckingham Street, Strand, London, W.C. 2.

ALLOTMENT: J. F. The sample of clay you sent us is inert and dead, and quite unsuitable for the cultivation of any crop. Where this clay foams the subsoil you should not trench in such a way as to bring it to the surface, but keep on the surface the loamy portion you mention, enriching and deepening it by the addition of leaf-mould and rotted (not fresh) manure. You can also apply basic slag now, and leave it to work itself in during the winter. With regard to the gravel, this also makes poor soil for cultivation, and should not be brought to the surface, unless it is well mixed with loam, and forms only a small proportion in the conditions you have described. It is hardly probable that Onions, which require rather rich soil, would thrive; we should advise you to plant only a few as an experiment.

APPLE CULTIVATION: Blackheath. Maiden Apple trees frequently bear crops that look out of proportion to their size and strength. Of the statements made in the newspaper cutting we know nothing. You may make experiments.

Books as Christmas Presents.

There is nothing so helpful to a young gardener as carefully selected books written by successful cultivators in the various branches of gardening.

- Botany, A Year's.** Adapted to Home and School Use. By Frances A. Kitchener. With 195 Illustrations. 5s. 4d.
- China, A Naturalist in Western.** By Ernest Henry Wilson. Illustrated, in Two Volumes. £1 10s. 6d.
- Flora, British, Handbook of the.** By Geo. Bentham. Revised by Sir Joseph Hooker. Seventh Edition. 9s. 5d.
- Fertilisers and Manures.** By A. D. Hall, F.R.S. 5s. 5d.
- Insect and Allied Pests of Orchard, Bush and Hothouse Fruits.** By F. V. Theobald, M.A., etc. 328 Illustrations. 30s. 6d.
- Insects, Injurious and Useful.** An Introduction to the Study of Economic Entomology. By L. C. Miall, F.R.S. 100 Illustrations. 5s. 9d.
- Intensive Culture of Vegetables on the French System.** By P. Aquatias. Illustrated. 3s. 11d.
- Iris, the Book of the.** Illustrated. By R. Irwin Lynch. 2s. 10d.
- Johnson's Gardener's Dictionary.** New Edition. 9s. 6d.
- Judging, Rules for.** Issued by the Royal Horticultural Society. Latest Edition. 1s. 6d.
- Land of the Blue Poppy, The.** By F. Kindon Ward. With Illustrations and Maps. 12s. 6d.
- Landscape Architecture, The Art of.** By Samuel Parsons. A practical and authoritative work. Illustrated. 15s.
- Lawns.** By Sutton and Sons. Reading. In paper cover. Well Illustrated. 1s. 3d.
- Lawns and Greens.** By T. W. Sanders. A Guide to the Formation and Management of Lawns, Tennis Courts, etc. Illustrated. Paper. 1s. 8d.
- Lily, Book of the.** By W. Goldring. Illustrated. 2s. 9d.
- Little Gardens and How to Make the Most of Them.** By H. H. Thomas. A handy and useful work for the Amateur. Paper. 1s. 3d.; cloth, 1s. 9d.
- Mango, The.** By G. Marshall Woodrow. An account of its Culture and Varieties. 1s. 1d.
- Manures and the Principles of Manuring.** By C. M. Akman. 6s. 10d.
- Manures for Garden and Farm Crops.** By W. Dyke. Cloth, 1s. 9d.
- Manuring, The Science and Practice of.** By W. Dyke, with introduction by J. Wright. A most practical work for the Amateur, Market and Professional Gardener. 1s. 2d.
- Manuring of Market Garden Crops, The.** By Bernard Dyer and F. W. L. Shrivell. New Edition. 1s. 3d.
- Market Gardening, The Book of.** By R. Lewis Castle. Illustrated. 2s. 9d.
- Mendelism.** By R. C. Punnett, F.R.S. New and Enlarged Edition. 5s. 4d.
- Mendel's Principles of Heredity.** By W. Bateson, F.R.S. 12s. 6d.
- Mushrooms, and How to Grow Them.** By John F. Barter. An excellent Treatise. Illustrated. 1s. 2d.
- My Garden in Spring.** By E. A. Bowles, M.A., Chairman of Scientific Committee of Royal Horticultural Society. With Preface by Reginald Farrer. "Mr. Bowles . . . has the time to be his own gardener, and has thereby gained that first-hand knowledge of plants without which any writer on horticultural subjects is . . . apt to be neither interesting nor informing." Price 5s. 6d.
- My Garden in Summer.** By the same author. Price 5s. 6d.
- My Garden in Autumn and Winter.** By the same author. 5s. 6d.
- Orchids and their Cultivation.** By James O'Brien, V.M.H., Hon. sec. of the R.H.S. Orchid Committee. Contains 8 full-page Coloured Plates from colour photography. 1s. 10d.

WANTED, 1,000 Large ASPIDISTRAS.

Well plants, suitable for stock, cash or exchange. See our latest advertisement, catalogues free. SMITH, Loughborough Nursery, Loughborough Junction, London, S.W.

THERE is no more delightful occupation than the long evenings of winter, when, to make up a good fire, and take in one's hand a favorite book, this represents the acme of comfort, and a hard day's work "to reading," as in everything else, it is "everything to his taste," and the garden enthusiast, be he professional or amateur, will devote his winter evenings to a book which deals with the subject nearest to his heart, that of horticulture. And in this theme, old, yet ever new, no volume can give so much and such varied information within a short compass as a bound volume of the "Gardeners' Chronicle." On one page it tells of the latest discovery in horticultural science, and describes the rich harvest of new plants introduced into cultivation by intrepid plant collectors from the remotest parts of China and Tibet; on another page it relates the progress of the horticulturists of today in the raising of new plants by hybridizing; and, again, it tells the romance history of the latest records to the legion of plant pests. The "Gardeners' Chronicle" has been printing such records for over seventy years.

APPLES.—Wanted, from 30 to 50 bushels

of good sound Apples, Cox's, Benlomas, and other good keeping varieties, for cash, send samples; fair price given. ROBERT GREEN, 26, Crawford Street, London, W.

SOME 17th AND 18th CENTURY GARDENERS.

THE history of gardening must largely consist of a piecing together of many shreds. The subject is so full of ramifications, and spreads over so many centuries, that the gathering of the multitude of data is a matter of time, patience and research. Every student may contribute his share to the building of the fabric by taking up some unexplored line of research and by publishing the results of his inquiries. A complete history of the subject may be written eventually, and the future historian will be assisted by such details as can be brought to light in the meantime.

I have been able to glean a good many facts concerning gardeners of the 17th and 18th centuries from one of the most useful books of biographical reference ever printed—the six large octavo volumes published by the Harleian Society from 1899 to 1901, and generally known as Musgrave's *Obituary*. This stupendous compilation, which deals almost exclusively with British names, was the work of Sir William Musgrave (1735-1800); it remained in MSS. for nearly a century, and is now in the British Museum. Musgrave extracted his obituary notices from many hundreds of volumes, among others the *Gentleman's Magazine*, and biographical memoirs of all kinds. Musgrave observed no definite system of selection, but took whatever notices were printed, and threw the whole into an alphabetical arrangement. His system had the supreme advantage of preserving for us a very large number of names of men and women who, in a general way, were not celebrities, except perhaps in the minor walks of life. His volumes, as edited by Sir George J. Armytage, enumerate over 60,000 names, and give references to the

original sources of authority, where in most cases further and often very important additional information may be found. The work, in fact, may be described as an index to English obituary notices from the earliest times to the end of the year 1799.

There are some hundreds of names which are of interest to students of the history of horticulture and botany. This interest is naturally of a very varied character; and many gardeners are here recorded, not because they were famous for their technical skill, but for some extraneous reasons. For instance, to take the earliest name I have extracted: a certain Trestram who was a gardener at Brentford, Middlesex, and who died in 1619, at the age of about 76 years. He is enshrined in Fuller's *Worthies of England*, 1684, and in Winstanley's *Lives of the Most Eminent Persons in the English Nation*, 1660, and his title to notice is that, being "seized with an extreme fever and violent inflammation of the lungs, recovered after the loss of 60 ozs. of blood in three days"; he was under the care of Dr. Theo. Deodate, physician to Prince Henry and Lady Elizabeth, and to have been attended by a Royal medical man shows that Mr. Trestram was a personage of some importance. In the same year—1619—we have the record of the death of another gardener, Vincent Corbet, who has a double title to fame, first because he was the father of Richard Corbet (1582-1635), successively Bishop of Oxford and Norwich, and secondly, because his virtues have been immortalised in a fine epitaph by Ben Jonson. He lived at Twickenham, and was famous for his nurseries and plantations of trees. Jonson tells us:

"His mind as pure and neatly kept
As were his nurseries,"
and his own son, the Bishop, who ranks as a poet, further informs us:
"Years he lived well-nigh fourscore,
But count his virtues he lived more."

The Corbets, moreover, have another interest for us to-day, for Peter Corbet, "a descendant and worthy representative, bating the point of sanctity, of old, factious Bishop Corbet," figures in Charles Lamb's "Character of the Late Elia."

We may conveniently group together the names of the various men recorded by Musgrave who acted as gardeners to the Royal family. At the head of these in point of time is John Rose, who died on September 11, 1677, aged 58. He was chief gardener to Charles II., and in the Royal collection there is a portrait of him presenting the first Pineapple cultivated in England to the King. He is a familiar figure in the history of English gardening. In 1738 the *London Magazine* records the death, "of a dropsy, at his house at Kensington," of Charles Bridgman, "gardener of all his Majesty's Royal gardens, a place of considerable profit." A notice of him appears in Johnson's *History of Gardening*, and in the first supplement of the *Dictionary of National Biography*. He was succeeded by a Mr. Dent, concerning whom history is silent, and whose reign was apparently not long, for in the *Gentleman's Register of*

1749, the King's "master gardeners" are entered as Sam. Milward at Kensington and St. James's, and George Lowe at Hampton Court. In 1757 (September 2) the death occurred of Thomas Greening, gardener to George II., and his widow died at Turham Green in June, 1781, aged 70. The above-named George Lowe remained at Hampton Court until his death on November 24, 1758; and six years later (September 8, 1764) there was another death in the Royal gardens in Mr. Brian, who was kitchen gardener to the King. Evidently living in retirement at Molesey, and not far from the scene of his active labours, was Mr. Pettit, "master gardener at Hampton Court to King George I." (who died in 1727), and here he died on March 9, 1771; and another veteran passed away on September 10, 1772, in Mr. Sheppard, "gardener to the King," at the great age of 109.

A number of my extracts are of men who, like the last-named, were centenarians. John Storey, gardener to the Duke of Bedford, who died on April 9, 1770, reached the age of 105 years; Archibald Nisbet, of Aughtyfarmale, Co. Lanark (June 21, 1792), aged 103; a Bristol gardener of the name of Hobbes (1753), aged 107; an Exeter gardener, John Jackson (July 17, 1764), aged 113; R. Asley, of Streatham (June 7, 1782), "late gardener to Mr. Stallard," aged 100; John Hammond, of Maidstone (May, 1789), aged 100, "the oldest Freeman and inhabitant of Maidstone"; Anthony Noble, gardener to Henry Bevan, Esq., of Milltown, Ireland (May, 1790), aged 115; and, older than all, John Watson, park-keeper at Limehouse, Cheshire (April, 1778), aged 130. It may be questioned if all these centennial claims could withstand severe testing. The 18th century was an age of easy faith in such matters.

Southwark to-day does not suggest either nurseries or gardens, yet two centuries or more ago it must have been an agreeable suburb of the City. What was formerly Kent Street, and is now Tabard Street, is full of historical associations; it was the route taken by Chaucer's pilgrims, and through it the Black Prince conducted the captive French King; but in the 18th century Smollett described it as "a most disgraceful entrance to such an opulent city." It was near Kent Street Turprike, on October 11, 1736, that a florist of the name of Jones came to an accidental death. He had, according to the *Gentleman's Magazine*, "several times been robbed of valuable flower roots," and "had provided a gun with several wires to the trigger that when touched would go off," and scare the intending thieves; he unfortunately forgot the trap which he had set for others, and fell a victim to his own contrivance. Ten years later (June 17, 1746), we read of the death of Richard Atkinson, gardener, of Southwark, at the age of 90, "worth £30,000." He was probably a gentleman who resided in the district, who made a hobby, rather than a business, of gardening. Rotherhithe, too, has its horticultural celebrity

in John Warner (he died February 24, 1760, aged 86), who lived in East Lane; he is described as "a gentleman eminent for his skill in the most curious articles of horticulture." I identify him with the Warner mentioned in Hughson's *History and Survey of London*, as having attempted to restore the cultivation of vineyards in England. Observing that Burgundy Grapes ripened early, and conceiving that they might be grown in England, Mr. Warner obtained some cuttings which he planted as standards, and, although the soil was not particularly good, he, with care and skill, was so successful that he obtained crops so ample that

have the record of the death of "William Smith, Esq., a curious florist," at South Lambeth, probably a private resident with a large garden rather than a tradesman. Another "eminent florist," a Mr. Dennet, died in the same parish on April 18, 1739; and in November, 1745, the *London Magazine* announced the death of Mr. Kingman, "Master of the Artichoke Alcubouse in Lambeth Marsh, and the most eminent florist in England." The combination of the two callings of publican and florist is distinctly unusual, but it is not unique; for instance, in that somewhat scandalous little book, *Memoirs of the Green Room*, 1814, we are told

of dog-bites, Abraham Spencer at Twickenham, 1747, and Mr. Jackson at Fulham, 1778; Joseph Longhurst, a Chertsey gardener, who died June 12, 1769, aged 69.

London seedsmen figure somewhat prominently in my lists, and most of these had shops in the Strand. The earliest of these was "J. Foster, Esq.," "formerly a seedsmen in the Strand," who died at an advanced age at Cheshunt, Herts, January 2, 1781. Both Mr. Ferno (of Ferno and Thatcher, seedsmen and net makers, 147, Fleet Street) and his wife died within nine hours of one another on March 30, 1782. Two years later (November 5, 1784) we have the announcement of the death of Warren Luker, seedsmen and nurseryman, of City Road. Alexander Eddie, the founder of the firm of Eddie and Dupin, seedsmen, of 68, Strand (in 1783 the firm was Eddie, Taylor, and Chambers, and in 1795 Wright and Beck), died at Lambeth May 3, 1788. Charles Minier, the founder of one of the longest lived firms of seedsmen in London, at 63, Strand, died at Kew on March 22, 1790, the firm existing until our own times.

Two at least of our names may rank as those of pioneers, if the claims of those who wrote their obituary notices hold good. For a Mr. Evans, of Kilbroyth, Montgomeryshire (May, 1774), it is stated that he first introduced the culture of Turnips into Wales; whilst for Henry Prentice, who died at Edinburgh, January 24, 1788, aged 85, the claim is advanced that it was he who first introduced the cultivation of Potatoes into Scotland. It is very difficult to accept this statement. A selection of other names can only be dealt with briefly. Thomas Engeham, a gardener, who died at Canterbury, March 4, 1792, claimed to be a lineal descendant of Sir Thomas Engeham, of Goodneston, Kent, who died in 1611, and of whom an account appears in *Hasted's Kent*, Vol. III. From Frome, in Somersetshire, came the announcement of the death, on March 24, 1774, of John Moody, "an ingenious florist," who "won the prize at the Florists' Feast for upwards of thirty years past." The death of another noteworthy man, Mr. Close, gardener to John Fuller, Esq., of Rosehill, Sussex (January, 1788), "remarkable for his skill in the management of hot-houses," calls for notice, not so much for what he accomplished as for the extraordinary man by whom he was employed—"Jack Fuller," as he was generally called. Fuller, who died in 1834, was a stormy petrel in Parliament. He was committed to the Tower for insulting the Speaker, and on receiving an offer from Pitt of a peerage is reported to have thrown the letter into the fire, exclaiming "Jack Fuller I was born, and Jack Fuller I will die." He was a patron of Turner, the artist, and erected an observatory and several ornamental buildings in his park and gardens, where Turner painted several pictures. Some account of Jack Fuller was published in the *Times* of March 19 and 23, 1908; and if all the stories which have been told of "Jack Fuller" are true, Mr. Close, as his gardener, could not have lived in a bed of Roses. *W. Roberts.*

(Drawn by Miss Frances Bunyard.

FIG. 90.—RED CURRANT VICTORIA ($\frac{1}{2}$ NAT. SIZE).

(see p. 237.)

it afforded him upwards of 100 gallons annually, and he furnished cuttings to growers in many other parts of England. The memory of a famous botanist is recalled by the announcement of the death at Stratford in March, 1781, of John Morrison, "an ingenious botanist" and principal gardener to Dr. John Fothergill (who himself died in the December previously), whose celebrated garden was at West Ham. Fothergill's name is to be found in most biographical dictionaries, but that of Morrison, to whom probably Fothergill owes much of his fame as a botanist, may be sought in vain.

Lambeth's celebrity for its gardens and nurseries is well known, and in March, 1738, we

that the Drury Lane actor, Mr. Penson, was the son of a nurseryman and seedsmen, who also kept the Red Lion Inn at Chester. At least one of Lambeth's nurserymen developed into a very big swell indeed, for Thomas James, of Cupor's Bridge, Lambeth (opposite Somerset House), who died on January 2, 1791, was in the Commission of the Peace for Surrey, and Sheriff of that county in 1774. Islington had a nurseryman in William Watson, who died on January 29, 1795, aged 75; Brompton, one of many in Joseph Kirke (July 1, 1791); and at Molesey John Villet (April 1, 1769) is described as "famous for raising Pineapples." Two of our names are of gardeners who died from the effects

FRUIT REGISTER.

A GOOD LATE PEACH.

It may interest some who are contemplating planting Peach trees this autumn to know of a first-rate variety which is, I think, very little cultivated. I purchased trees some 25 years ago from Messrs. J. Veitch and Sons, under the name of Marquis of Downshire. This tree is still producing good crops in an unbeated house facing west. When the tree is not heavily cropped the fruits are of large size and good colour, and, what is often lacking in late Peaches, of good flavour. Some years I have realised 12s. per dozen for the fruits in Covent Garden late in September. *W. Peters.*

A REVISION OF THE RED CURRANTS.

(Continued from page 232.)

THE DUTCH GROUP.

THESE varieties of the Dutch group have flowers of the vulgare type, and the leaf is large and rather like Versailles in pose but lighter green in colour, nearly all being a light pea-green.

DUTCH.—Syns. Old Dutch, Red Champagne, Goliah.—*Flowers.*—Vulgare type, rather large, slight ring, greenish-yellow; sepals apart, petals wedge-shaped, buds quite green, rachis glabrous.

Leaves.—Young slightly brown, rather hairy in this stage, adult, pea-green, rather large, upward folded, but not so much as Scotch, boldly serrate.

Fruit.—Bunches long, stem long, often 1½ inch, fruits medium size, pedicels short, rather stiff, so that the fruit is held to one side, calyx rather prominent.

Season.—Medium.

Buds.—Round pointed, well away, slightly hairy.

Growth.—Vigorous, rather upright. Very free cropping.

Origin.—A Dutch Currant has been known for several centuries, but it is impossible to say if it is this one. The variety I have described I have received from many sources, all labelled as Dutch, so there is little doubt that it is generally known under this name. The Currant known on the Continent as Dutch is Prince Albert, described in the *Petraeum* group.

UTRECHT.—*Flowers.*—Vulgare type, pale yellow, sepals well apart, hardly folding back, petals wedge-shaped, rachis slightly downy and with a few dark glandular hairs.

Leaves.—Young state slightly brown tinted, adult yellowish green, a little inward folded.

Fruit.—Bunch medium, stem quite half total length of bunch, rachis very stout, slightly downy, fruits hang loosely.

Buds.—Rather small, dull brown, close to wood, very slightly hairy.

Season.—Medium.

Growth.—Strong spreading, internodes rather short.

Origin.—Unknown.

This useful Currant is at first sight very like the Dutch but the long stem of the bunch and the more spreading growth serve to distinguish it from the type variety.

PERFECTION (LAXTON).—*Flowers.*—Vulgare type, green, sepals overlapping, petals T-shaped, rachis almost glabrous.

Leaves.—In young state slightly brown tinged, adult greenish green, very rugose.

Fruit.—Bunch very long, berries very large, of even size, held lively, rachis unusually stout and keeps green.

Season.—Mid to late.

Buds.—Rather small, roundish, dark brown, away.

Growth.—Very stout and vigorous.

Origin.—Raised by Messrs. Laxton Brothers and introduced in 1910. This proves to be the finest Currant of recent years, as the fruit is large without special culture, keeps a bright red even at the end of August, and is extremely prolific. From the character of the leaves it seems to be of the Dutch type crossed with Ruby Castle. The American variety of the same name described under the Versailles group is quite different, and with me greatly inferior.

SKERREIN'S EARLY.—This resembles the Dutch very closely but is earlier; the bunches do not have the long stem of Dutch, the rachis turns yellow and the fruits decrease in size, more to the end of the bunch. A distinct and vigorous variety much grown in Kent for early market use. Origin uncertain, but probably raised in Kent.

VARIETIES OUTSIDE THE GROUPS.

KING'S RED.—There are several Currants of this name in commerce, but they have proved

so different, varieties of the *petraeum*, *rubrum* and *vulgare* groups all bearing this name, that I have been unable to select any one as the true type.

The varieties described below are "mono typic," and do not fit in to any of the groups previously described.

VICTORIA (see fig. 90). Syns., Wilson's Lang-Bunch, Houghton Castle (in error), Langtraubige, A longue grappe.

Flowers.—Vulgare type, ring marked, sepals well apart, petals markedly wedge-shaped, rachis almost glabrous, buds green.

Leaves.—Brownish tinged when young, adult a little yellowish, held flat and very lax and irregular, petioles long.

quite greenish yellow, sepals not touching, much folded back, petals wedge-shaped, slightly downy, with a few glandular hairs.

Leaves.—Young state, yellowish-green and malt, with faint brown tinge, later they are very dark green, rugose, held nearly flat, coriaceous.

Fruit.—Bunches rather long, berries large, of even size.

Season.—Early.

Buds.—Pointed, a little away, slightly hairy.

Growth.—Rather spreading.

A very distinct variety, one of the earliest to start growth, and by its dark green coriaceous leaves stands out as distinct from any other kind. From the leaves alone one would suspect a *petraeum* × *vulgare* cross, but no

(Drawn by Miss Frances Bunyard.)

FIG. 91.—RED CURRANT FERTILITY (½ NAT. SIZE).

Fruit.—Bunch long, but the stem is unusually long, often 2 inches, making it appear longer than it really is. Rachis glabrous, turns yellow, berries inclined to be held to one side.

Season.—Very late.

Buds.—Remarkably long and thin, dark brown, away, glabrous.

Growth.—Very straggling and uneven. Moderately fertile.

Origin.—I have not been able to discover the origin of this variety, but it is probably well over 100 years old.

This cannot be the Victoria which was confused with Ruby Castle, and I expect May's Victoria was probably Houghton Castle. The stock of this variety seems fairly true.

LA TURINOISE.—*Flowers.*—Vulgare type,

evidence of this is found in any other part of the plant.

FERTILITY (see fig. 91). Syns. Le Fertile, A gros Fruit Rouge.

Flowers.—Vulgare type, sepals well apart, much turned back, petals slightly wedged, eye a little red.

Leaves.—Young, decidedly brownish, very early starting. Adult, pale green.

Fruit.—Bunches remarkably long, often as many as 25 flowers, rachis slightly woolly, berries held on one side. *Season.*—Late.

Buds.—Small, round, a little away, scales edged hairs, dark chestnut-brown.

Growth.—Moderate, upright.

Quite the longest bunch in my collection.

H. A. Bunyard.

ON INCREASED FOOD PRODUCTION.

GROUND OPERATIONS.

On p. 200 Mr. C. Davis seems to imply that he believes it to be good policy to dig light ground early. On p. 215 Mr. J. Paice states that the digging of light soils early is a mistake. Which advice is the more sound? I believe that of Mr. Paice to be correct; certainly it is the practice most generally followed. There may be occasional times when the accepted methods of dealing with soils may seem at fault—some peculiarity of texture requires that the rule shall be reversed. But 99 out of every 100 times there can be no doubt it is best to trench heavy land as early in the season as possible. When heavy ground is dug rains pass away more quickly, air has a longer time to permeate the moved layers, and frosts, winds, and sun, effect a disintegrating influence on the mass. Some gardeners when trenching or digging heavy soils omit to break or loosen up the soil in the bottom of the trench, which makes all the difference to the condition of the top soil. Light soils should not be prepared until spring is approaching, because they do not require the same disintegrating process as heavy land, and also because there is the danger of valuable food being washed away in the drainage water. C. Turner.

ALLOTMENTS.

It is essential that there should be a large increase in the number of allotments throughout the country before next spring, and the Commissioners have been asked to give all the assistance they can to see that any unmet need demand for land for this purpose is met as far as possible.

In urban districts and non-county boroughs the local authorities have adequate powers to take over land for allotments, subject, in the case of occupied land, to the consent of the County Agricultural Executive Committee. In county boroughs no such consent is required. Most urban local authorities are exercising their powers wherever necessary, and arrangements have been made by the Department for this work to be stimulated and supervised by officers of the Department.

The number of allotment plots so far reported as laid out under the Cultivation of Lands Order in England and Wales is 183,004. In Surrey alone over 1,000 acres of additional allotments have been provided under the powers exercised by the Food Production Department and the local authorities.

MUSHROOMS.

It is a little surprising that Mushrooms are not more extensively cultivated in this country than is the case. When one takes into consideration the large demand for them throughout the year, the good prices invariably obtained for them, and their value as a food, combined with their extremely appetising quality, it is strange that larger numbers do not grow them wherever horse-manure is obtainable easily. Old Mushroom-bed manure is one of the most valuable materials for nearly every branch of gardening, consequently there is no waste in the manure used for the beds.

Many may be under the impression that it is a costly proceeding, and that unless one is provided with elaborate Mushroom-houses this useful fungus cannot be satisfactorily produced. This, however, is not the case, as, with a little experience, large crops can easily be produced in any out-of-the-way building, disused cellar, or even in the open; indeed, it frequently happens that much better crops are obtained when grown in such conditions.

One of the most important rules to observe is to place the material for the beds under cover and turn it a few times to sweeten it. The

short litter should not be removed, as this is beneficial rather than otherwise. In placing the material together to form the bed it can scarcely be made too firm. The spawn should be obtained from a reliable source. It should be broken into small pieces and buried at regular intervals when the bed is at a temperature of 70° to 80°. After about a week the bed should be soiled, using, if possible, the top spit of an old pasture, which should be broken up finely, or passed through a coarse sieve, using as much fibre as possible. It should be spread to a depth of 1½ to 2 inches, and beaten perfectly level with the back of a spade or shovel. When the bed is made in a cool shed, or in the open, a good thickness of stable litter should be placed over the whole, and the beds should never be allowed to become too dry. In six weeks or two months the Mushrooms should begin to appear. Never cut the stalks with a knife, but simply twist them off when gathering the crop. When the bed shows signs of exhaustion give a thorough watering with diluted liquid manure from the farmyard, warmed before being applied. Edwin Beckett.

POTATO TRIAL.

The following results of a careful trial of Potatoes may prove of interest to readers of the *Chronicle's* *Chronicle*. The tubers were grown in shallow soil over chalk, with stable manure added at the time of digging, but no artificial manure was used. The haulm was sprayed three times during the season. The results show that seed tubers of large size do not produce the heaviest crop, also that new seed is essential. M. Nicholls, St. Clare Gardens, Kensington, near Strewnok.

Variety Up-to-Date, planted April 26:

Six seeds, 1 oz. weight; crop 36 lbs.; heaviest tuber 17 oz.; sample 2nd.

Six seeds, 2 ozs. weight; crop 41 lbs.; heaviest tuber 24 ozs.; sample 1st.

Six seeds, 3 ozs. weight; crop 24 lbs.; heaviest tuber 11 ozs.; sample equal 3rd.

Six seeds, 3 ozs. weight (sprouted before planted); crop 25 lbs.; heaviest tuber 15 ozs.; sample equal 3rd.

Six seeds, eye with section of tuber; crop 18 lbs.; heaviest tuber 15 ozs.; sample 6th.

Planted May 1, from pots inserted in pots one month previous:—

Six eyes, with only skin attached; crop 20 lbs.; heaviest tuber 9 ozs.; sample 6th.

Six cuttings; crop 25 lbs.; heaviest tuber 17 ozs.; sample 4th.

Planted April 26:

Arran Chief, 4 rows, 1 oz. weight seed, 14 lbs. new seed, crop 4 cwt. 77 lbs.

Arran Chief, 5 rows, 1 oz. weight seed, home saved; crop 3 cwt. 50 lbs.

King George, 14 lbs. home saved, mixed sized seed; crop 1 cwt. 62 lbs.

King George, 14 lbs. new seed, mixed sized seed; crop 3 cwt. 70 lbs.

Sharpe's Express, new seed, 14 lbs.; crop 2 cwt. 56 lbs.

British Queen, new seed, 14 lbs.; crop 4 cwt. 37 lbs.

Harbinger, new seed, 14 lbs.; crop 2 cwt. 34 lbs.

Epicure, new seed, 14 lbs.; crop 3 cwt. 5 lbs.

Windsor Castle, new seed, 14 lbs.; crop 2 cwt. 95 lbs.

SUGAR BEET.

The British Sugar Beet Co., which has acquired an estate near Newark for the purpose of growing Sugar Beet under the auspices of the Board of Agriculture, takes possession of the estate at Lady Day next. For various reasons it will be impossible to put the greater part of the land under Beet for next season, and the company hopes to utilise 1,500 acres for corn.

THE KITCHEN GARDEN.

By J. DUNN, Foreman, Royal Gardens, Windsor

EARLY PEAS.—As soon as the ground is dry enough a sowing of early Peas may be made on a sheltered border the soil of which has been trenched and prepared for the purpose. For this sowing narrow trenches may be made to the depth of 6 inches and the soil placed in a position to afford protection from cold winds during the spring, as young Pea plants are more frequently injured by rough winds in spring than by frost. Sow the seeds thicker than is usual for later crops and cover them with 2 inches of fine soil. A sharp watch should be kept for pests, as much injury may soon be done if these pests are not destroyed. The Pilot is a suitable variety for present sowing, and a space of 5 feet should be allowed between the rows.

CAULIFLOWERS.—Frames containing Cauliflower plants in pots intended for planting out in April should be freely ventilated whenever the weather is favourable. On mild days the lights may be removed entirely early in the day and replaced at night. Examine the plants frequently for watering, and when moisture is necessary soak the soil with soft water. A cold brick pit is the best place in which to winter the plants, but a protective covering must be used to ward off frost. Slugs should be kept in check by placing lime round the edges of the bed. Seedlings still in the seed bed should be carefully potted or pricked out in boxes for successional cropping. If the stock of these plants is short make a sowing of a good early variety at once in boxes or pans and germinate the seeds in a house or pit having a temperature of 50°. When the seedlings are large enough to handle they should be transferred to 3-inch pots and grown in a slightly heated pit close to the roof-glass. Dean's Early Snowball and Great Dane are two excellent varieties.

ENDIVE IN UNHEATED PITS.—In order to maintain a supply of blanched heads a number of plants may be covered with sheets of paper, over which a layer of dry Bracken Fern should be placed to ensure perfect darkness. Keep the atmosphere of the pit as dry as possible.

LETTUCES IN PITS.—Pits in which Lettuce plants are well advanced should be freely ventilated and the soil lightly stirred with a small hoe to prevent damping. The plants should be protected during frosty weather.

FORCING OF CHICORY.—Continue to lift roots of Chicory and place a batch in heat every eight days. A dark chamber with a dry atmosphere is necessary, as the young leaves soon decay if subjected to an excess of moisture. When the roots are placed in the forcing quarters keep the crowns clear of the soil, which should be made firm round the lower part of the roots. If only a small supply is necessary the forcing may be done in pots.

AUTUMN CAULIFLOWERS AND BROCCOLI.—These crops should be protected during frosty weather. If the plants have been lifted with a good quantity of soil adhering to the roots and placed closely together their protection will be a simple matter, provided sufficient clean covering material is available. Dry Bracken Fern is a useful material for the purpose, and should be laid lightly over the plants, but removed again as soon as the weather turns warmer. In lifting the plants for replanting closely together exercise great care, and place the roots deeply in the soil. We are cutting good heads of Halloween Giant Cauliflower, which are well protected by their own foliage.

LATE TURNIPS.—Late Turnips which are of sufficient size for use may be lifted and placed under cover for use during the winter. If protected from frost very late Turnips still under-sized may be left in the ground all the winter.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

ZYGOPETALUM.—The partially developed pseudo-bulbs of *Zygopetalum Mackayi* are now sending out their flower spikes, and, from now onwards until the flowering season is over, extra care must be taken in watering the roots, for an excess of moisture may cause the leaves to become spotted. Water should only be applied when the compost is dry, and sufficient should be given to soak it thoroughly. When flowering is past or the spikes are cut the plants may be repotted if necessary, and as it is a free, deep-rooting species, plenty of pot-room and a good depth of compost are required. The pots should be filled to about a quarter of their depth with drainage materials; a mixture of good turfy loam and Osmunda or A1 fibre, with plenty of crushed crocks mixed in, will form a suitable potting medium. Pot the plants, with the compost up to about half an inch of the top of the receptacle, and place a layer of the compost and Sphagnum-moss, chopped rather short, over the surface. This species generally does best in a warm, stove-like temperature. *Zygopetalum orinatum*, Z. Clayi, Z. Perseoudii, Z. Burkilli, Z. Gottiannum, *Zygocaulis Wigandiana* and Z. Charlesworthii are in full growth, and should be afforded liberal supplies of water at the roots until their new pseudo-bulbs are completed, and should be grown in a cool, shady position in the intermediate house. *Zygopetalum Ballianae*, Z. rostratum and Z. Roebingianum should occupy a position near the roof-glass in a moister and warmer atmosphere. The surface moss should be given frequent sprinklings in order to keep it in a healthy condition. Z. Ganten and Z. maxillare will be producing roots from the base of the young growths, and plants that require increased rooting space should be given attention. These two species have a rambling habit of growth, and are not suitable for growing in pots or pans; they do best if fixed to a portion of the stem of a tree fern. If necessary, the rooting space may be extended by wiring another piece of stem on the top of the old block, and the plants should be suspended in a moist, shady position in the warmest part of the intermediate house.

THE HARDY FRUIT GARDEN

By W. A. COOK, Gardener to the Hon. ARTHUR J. DAVEY, Abhors Wood, Galding, Surrey.

BERRY BEARING PLANTS. Blackberries should be planted as soon as possible, and the stakes or wires for training should be in readiness. The Loganberry is probably the most popular of berries, and the most prolific and easy of culture. The Malin Raspberry and Blackberry is also a useful and good-flavoured fruit, and *Rubus phoenicolasus* is suitable for jam making. All these berry-bearing plants will grow in heavy soil and are, as a rule, very vigorous.

ORCHARDS.—All the weak growths should be cut off from orchard trees that are in a bad condition, more especially from the centre of the tree. Expose every branch, if possible, to the sunshine, remembering that one bushel of good fruit is equal in value to three or four bushels of inferior quality, whether for market or for home consumption. Inferior trees should be rooted up and replaced by young and vigorous trees. Some carefully selected varieties should be planted, of which the fruit can be used from January to April.

FIG TREES.—In very cold districts Fig trees should now be unfastened from the wall and their branches tied together to keep them as inactive as possible. In very severe weather the branches should be protected by means of old mats, burlap, heather, or any dry material that is at hand. It must be fastened securely, so that the wind will not blow it out of position. Figs need a restricted root area. Should root-pruning be necessary it may be done at any time now, when the weather permits. Plenty of old mortar rubble should be placed about the roots, and the soil made very firm. The best variety for

outdoor culture is Brown Turkey. Negro Largo is a finely flavoured variety, and in some places does exceedingly well on a warm wall. Bruna Ischia is another desirable variety, and White Ischia does well, but the fruits are small. White Marseilles bears large, rich fruits, but is a shy bearer out-of-doors until the trees are of considerable age. Fig trees should be planted in poor but sweet soil, on well-drained land. A sandy soil in which are incorporated plenty of bricksbats is one of the best rooting mediums, and liquid manure should be supplied during the season of growth.

FRUITS UNDER GLASS.

By JAS. HUSOX, Head Gardener at Gunnersbury House, Acton, W.

VINES IN POTS FOR EARLY FORCING.—There is no better method of obtaining ripe Grapes by the end of May than to force pot vines. Preparatory to starting pot vines, it will be as well to select some Oak or Beech leaves as a fermenting material. These can be put direct into the house, and the vines stood on but not plunged in them, for a few weeks to come. Bend the rods down at once, and use the syringe freely. A night temperature of 55° is suitable when the weather is above freezing point. With frost the temperature may be somewhat lower. Varieties suitable for early forcing are Black Hamburgh and Royal Muscadine.

THE CHERRY HOUSE.—In previous notes I have given details of the management of Cherry trees in pots. The cultivation of these trees is profitable, for the house in which the plants are grown may be used from the end of June until the end of January for other purposes. At Gunnersbury House Figs are grown in the Cherry house until November, and at the present time it is used for Palms, whilst, if occasion arose, late Chrysanthemums could be grown in it. Span-roofed houses are best for pot Cherries, and they are suitable for trees planted out. A three-quarter span house is also suitable. With Cherries under glass the fruits will hang for some considerable time after they are ripe, and by a judicious selection of varieties the season may be made of considerable length. The cost of growing Cherries indoors is less than in the case of either the Peach or Nectarine, and they form an agreeable addition to chocolate sort fruits from the latter part of April until the earliest sorts are ripe on open walls during the month of June. Where too many indoor Peaches and Nectarines are grown one of the houses might well be planted with Cherries. Only a little fire-heat is needed, but an abundance of ventilation is necessary, for the Cherry is impatient of a close atmosphere. I prefer to have the bottom of the border covered, for excessive vigour in growth must be guarded against. The soil should consist of rich fibrous loam of an encaustic character, and beyond some old mortar rubble nothing else need be added. A border of not more than 24 feet in depth is preferable, but let this be made up piecemeal, as in the case of vines. Varieties suitable for successional cropping are (black) *Orange d'Annonay*, a first early variety, followed by Early Rivers and Late Black Bigarreau (coloured varieties) Governor Wood and Englemore. Early Bigarreau, with Bigarreau Napoleon as a later sort. All the varieties mentioned are excellent croppers. Our collection includes a tree or two of May Duke, for the sake of the pollen. The double or triple cordon is the best form of tree; these are easy to control, very simple in training, and they come into bearing sooner, in average conditions, than other styles of tree.

THE FLOWER GARDEN.

By W. J. GIBBS, Gardener to Mrs. DEMESTER, Keele Hall, Staffordshire.

VIOLETS IN FRAMES.—During the next few months pay strict attention to ventilating the frames in which Violets are grown. If the frames are heated, use just sufficient fire heat towards evening to dry up an excess of moisture. The top of the light should be raised a little at night and the heat turned off next morning, except in severe weather. Remove all

dead and decaying foliage at frequent intervals, and stir the soil lightly with a hoe or small hand fork. Small black slugs are a pest of the Violet, and difficult to detect at night, but they may be kept in check by light dustings of soot. Flowers of sulphur will keep mildew in check, and light dustings of fresh lime over the surface of the soil is a good preventive of spot disease.

RENOVATING OLD SHRUBBERIES.—The pruning, cleaning and forking of shrubberies which have been in existence for many years can be done at this period, when weather conditions make it impossible to carry out the usual routine. If the specimens of Laurels, Yew, Hollies, Privet, and similar shrubs are very old, however carefully they are pruned, the effect is poor; in such cases grub out these old trees, thoroughly prepare the ground, and replant with better varieties. The ground must be trenched and enriched with a liberal dressing of decayed manure. With the exception of fallen leaves, which should be dug into the soil, all rubbish should be burnt, and the ashes scattered over the surface. If it is necessary to retain some of the old specimens, they may be headed back to within 3 or 4 feet of the ground, and in certain cases even less, without fear of injury. Space may be reserved in the foreground for herbaceous plants. Care must be taken to prepare these spaces thoroughly, as they are usually full of fibrous roots from the shrubs.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to Lady NORTHCOLE, Eastwell Park, Kent.

PLANTS IN FRAMES.—Plants in cold frames should be matured carefully. In some cases little or no water will be required before the New Year. Ventilate the frames freely in mild weather, and remove all decaying foliage. Arrange the plants thinly apart, and if they are growing (as distinct from resting), place them near to the roof-glass.

CHRYSANTHEMUMS. All but the very latest varieties of Chrysanthemums are past their best, and plants that are over and not required for stock purposes may be discarded. Cut the stems down to within a few inches of the soil, and place the stools in a shallow frame, or light glasshouse, near to the roof-glass, for sturdy cuttings invariably make the best plants. The latest batch, for blooming about Christmas and the New Year, may be arranged with other plants in the conservatory. Keep the atmosphere of the houses dry; this may be accomplished by watering the plants early in the day and mopping up the water that drains from the pots. Ventilate much or little, according to the weather conditions, and keep the house freely aired in mild weather.

THE PROPAGATING HOUSE.—After the autumn batches of cuttings from stock plants are struck the propagating house will not be required much for the present. Advantage should be taken, while it is comparatively little used, to cleanse the woodwork and glass thoroughly. Clear out all hot bed or plunging material, which often becomes infested with wood-bore, cockroaches, and similar insects. Before bringing fresh plunging material into the house, dust under the pipes and stages with vermin powder or soil fumigant. Having finished the cleaning, use may be made of the house almost immediately, by inserting a batch of Carnation cuttings. Carnation plants that are now flowering usually furnish the best shoots for cuttings at this season, the growth being healthy and vigorous, and not too hard. In proper conditions they will strike readily, and they root freely in shallow boxes or pans filled with sand. Water the cuttings thoroughly once, and keep their tops fresh by occasional dampings, but on no account keep the sand saturated with moisture. The temperature of the house should range between 55° and 60°. To get good plants for blooming next winter, a long season of growth is required, for Carnations will not be hurried into growth. One cannot make up for lost time in growing Carnations. The main lines to follow are, to propagate early and grow the plants on gently all the season.

EDITORIAL NOTICE.

Editors and Publisher.—Our correspondents would oblige by delaying in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.9.

ACTUAL TEMPERATURE:—*Gardeners' Chronicle* Office, 41, Wellington Street, Covent Garden, London, *Thursday*, December 13, 10 a.m.: Bar, 29.9; temp., 45.0°. Weather—Fair.

SALE FOR THE ENSUING WEEK.

WEDNESDAY—

Balls at 67 and 68, Cheapside, at 3 o'clock, by Protheroe & Morris.

Food Production.

An appeal to horticulturists which has been made by Sir Arthur Lee, Director of Food Production, has been forwarded to Fellows of the R.H.S. by the president and council, and the text of the appeal, with the accompanying letter from the R.H.S., is printed below. The letter demonstrates the serious necessity for increasing the production of food by small cultivators as well as by farmers. Readers of the *Gardeners' Chronicle* are aware that we have consistently urged this course upon all those who have, or can obtain, the necessary facilities, and we again urge it. As Sir Arthur Lee says in his letter, all the food which can be produced will be wanted, and it behoves everyone, not only to produce as much food as possible, but also to exercise the greatest care in its use and distribution. Gardeners in particular, who are experienced cultivators, should devote as much space as possible to the growing of early crops, and in particular early and second early Potatoes of those varieties of which there is a plentiful supply of seed. By this means they may raise fresh food supplies at a comparatively early date, and may use the ground which has produced them for successional crops. We understand that the object which the Horticultural Division of the Food Production Department has set itself

to achieve is the doubling of the area under small cultivation. The task which lies before us is clear. In order to ensure that the total shall be doubled, it is necessary that everyone who already has ground available, should endeavour to triple his own area under vegetables. Special efforts are being made to increase the allotments in urban areas, and thereby to bring new land under intensive spade cultivation. Every gardener should become a missionary on behalf of the cause of garden and allotment cultivation. There is still time to bring fresh land into cultivation. The results obtained last year showed that even where it was not possible to turn up land under grass before the early spring, good crops were obtained; needless to say, however, the sooner the work of preparation is taken in hand, the better the chances of success. Another direction in which gardeners can help is by raising seedlings under glass, for planting out in the spring. Local organisation should render it easy to ascertain the total number of plants of the different kinds which can be raised in this manner, and also to secure their distribution to those who are prepared to grow them. We trust that every owner of a garden, and every gardener, both professional and amateur, will give serious heed to the authoritative appeal which has been addressed to them, and will help the Food Production Department to achieve the object which it has in view.

Royal Horticultural Society,
Vincent Square,

Dear Sir or Madam,—The enclosed letter from Sir Arthur Lee, Director-General of Food Production, sets forth in clear language the great urgency of making yet further efforts to increase food production.

The Fellows of the Society have already done invaluable work in this direction, but if sufficient supplies of food are to be produced during the coming year still more energetic efforts will be required.

We therefore trust that you will give the fullest possible practical effect to Sir Arthur Lee's appeal, and that, in addition to increasing so far as is possible the vegetable cultivation in your own garden and grounds, you will bring the contents of the letter to the notice of all others in your neighbourhood who would be able to render a similar assistance to the State.

GRENFELL,

Vice-President.

BALFOUR OF BUREIGH.

LAMBOURNE,

JAMES W. LOWTHER,

Members of Council.

W. WILKS,

Secretary.

November 16, 1917.

Dear Sir or Madam,—The harvests have been in large part gathered in. The food produced this year by the chief countries of the world is known, and the quantity of food required by this country and its Allies is also known. From this knowledge it is clear that the security of the nation demands that the greatest possible effort towards increased food production should be made.

It is on the farmers of the country in the first place that this task falls, but the country must also look to horticulturists to bear their share in it. The yet further increase in food production by horticulturists—both amateur and

professional—is of vital importance. The small cultivator has shown this year what considerable contributions he can make to our food supplies. Our needs next year will demand yet further contributions from him, and I therefore appeal most earnestly to every horticulturist—to the amateur and professional gardener, nurseryman, florist, fruit-grower, and to the allotment-holder—to do everything that lies within his power to increase the supply of food, to leave no garden ground uncropped, and to use every available glasshouse and frame for the purpose of food production.

If everyone possessing garden land and even partial leisure will do his utmost, horticultural food production may be increased far beyond the already remarkable stage to which it has attained during the past season. The present is no time for spending labour on the mere preservation of garden amenities, on the rolling of paths, the tending of lawns, or the planting of flower-beds, or the maintenance of glasshouses for the cultivation of shrubs and flowers, with the possible exception of such rare and valuable plants as the labours of a lifetime might not be able to replace. The situation demands that all these pleasures of the garden should be foregone, and that the whole energy of the gardening community should be devoted to the growing of food.

I appeal, therefore, to all owners of and workers in gardens to concentrate their energies on the vitally necessary work of increasing the area of ground under vegetable cultivation, and of using to their fullest capacity all glasshouses and garden frames for the production of food crops.

For, more than ever before, the country will have need in the coming year of every ounce of food which can be raised in these islands.

A. LEE,
Director-General of Food Production.

NEW PLANTS AT EDINBURGH.—In No. XLVI. of *Notes from the Royal Botanic Garden, Edinburgh*, is continued the "Descriptions of New Plants in the Herbarium," from 251—350. These are all Asiatic and, with few exceptions, Chinese, having been collected by F. KINGDON WARD, G. FORREST, R. E. COOPER, E. E. MAIRE, PÈRE MONBEIG, A. HENRY, and several others, but mainly by FORREST. The plants described are mostly shrubs and small trees belonging to well-known genera, such as *Lonicera*, *Viburnum*, *Eunonymus*, *Osbeckia*, *Cotonaster*, *Spiraea*, *Eriobotrya*, and *Photinia*. Among less familiar genera are *Acanthopanax*, *Brassaiaopsis*, *Illigera*, *Stemona*, *Sabia*, *Brandisia*, *Myricaria*, and *Caryopteris*. Two new genera are described, namely, *Sporoxeia* and *Trailliaedoxa*. The former is allied to *Oxyospora-Melastomaceae*, *Trailliaedoxa* (*Rubiaceae*) is so named by Mr. W. W. SMITH in honour of Mrs. G. FORREST. It is a lowly shrub with small yellow, rosy-white or creamy-white flowers. We are glad to see other commemorative names. *Buddleia Fallowiana* is given to keep in memory Sergeant George FALLOW, 5th Batt., The Royal Scots, a former gardener on the staff of the Royal Botanic Garden, Edinburgh, who died in Egypt from wounds received in action at Gallipoli. *Pyrus Harrowiana* is named in honour of Mr. ROBERT LEWIS HARROW, head gardener of the Royal Botanic Garden, Edinburgh, since 1892.

GIFT OF FRUIT TREES FOR FRANCE.—A consignment of a thousand standard fruit trees, the gift of the Mayor of Huntingdon (Councillor H. PERRINS, of the well-known nursery firm of WOOD AND INGRAM), has recently been sent to France to re-plant the orchards devastated by the Germans. The gift forms part of a present of 10,000 trees from the nurserymen of England, organised by the Agricultural Relief of Allies Committee. The trees were grown at

Brampton, and comprised Pears, Apples, and Plums. Each tree, apart from bearing the name of its variety, also bears a label to the effect that it is a gift from Great Britain. The trees were packed in 50 large strawed bundles, and filled six railway trucks. All the trees were dug and packed by German prisoners.

WOMEN'S NATIONAL LAND SERVICE CORPS

—The annual report of this corps has just been received from 50, Upper Baker Street, where the administration is now being carried on. It is a record of good work well organised, and the cheerful letters from workers, which form a large portion of the report, show how well the women in the corps are performing their duties. We are informed that, now that the prejudice of the farmers against female labour has been largely broken down, the demand for such labour exceeds the supply.

ROOT CROP YIELDS FOR 1917.—The total production of Potatoes in England and Wales in 1917 is estimated at 3,339,995 tons, or 335,000 tons (33 per cent.) more than in 1916, and is the largest crop recorded since returns of the production of crops were first collected in 1855. The yield per acre, 6.37 tons, is three-fourths of a ton heavier than last year, two-fifths of a ton above the average of the last ten years, and has only been exceeded four times in the last 50 years. The yield per acre of Turnips and Swedes is estimated at 12.55 tons, or two-thirds of a ton below average, and 1.25 ton less than in 1916; the decline being due to the unfavourable weather of the early summer in the north-eastern counties. The total production, 12,163,624 tons, is 429,000 tons smaller than last year, but 350,000 tons heavier than in 1915. Mangelwurzels, on the other hand, are a very satisfactory crop; the total production, 3,481,573 tons, is 1,400,000 tons greater than in 1916, and the yield per acre, 21.59 tons, is about 2½ tons heavier than last year.

STABLE MANURE AT ARMY CAMPS.

—Enquiries have been made by the Food Production Department with regard to possible accumulations of stable manure from Army Camps in Surrey, Hampshire, Dorset and elsewhere. Generally speaking, it seems that all manure now made is being removed, but there are one or two dumps that were accumulated in the early days of the war. The Hampshire Agricultural Executive Committee is taking active measures in connection with the matter, and has obtained orders from local farmers for 18,000 tons to be carted from a dump at Pitt Corner, near Winchester. This manure is distributed within a radius of five miles at 3s. 6d. per ton, the Army providing horses and wagons, and the Committee lending soldier labour from the Winchester Depot.

FARMYARD MANURE.—In the year before the war the amount of farmyard manure used on the land was estimated at 37,000,000 tons, of a value of £11,000,000, nearly three times the value of all other manures whatsoever. Having regard to the general use of farmyard manure, it is probable that there is no other means which would be so calculated to increase food production as the more general improvement in the storage of this manure. In this connection the first point to realise is that the liquid excreta of animals is richer both in nitrogen and in potash than is the solid excreta. In the next place, as confirmed by the experiments* carried out by Dr. RUSSELL and Mr. L. H. RICHARDS the consolidation of the heap is a means of reducing loss. Similarly and no less important is it to store the heap under shelter. If the heap is both sheltered and made compact, loss of nitrogen is reduced to a minimum.

DEAR MUSHROOMS.—In respect to Mr. BREKKE's note on Mushroom cultivation on p. 233, and the high prices frequently asked for this highly flavoured and nutritious food pro-

duct, it may be noted that last week the retail price in the London stores was 3s. a pound.

RAFFIA AND CAMOUFLAGE.—It is stated in *Gardening* (Chicago, Nov. 1, 1917) that every ball of raffia in New York has been commandeered by the U.S. Army authorities, who have requisitioned it on behalf of the troops in France for the purposes of camouflage.

WOOD PIGEONS.—A considerable amount of damage has been done this year in some counties by wood pigeons, and in Derbyshire and Worcestershire, among others, drastic measures are to be taken for the suppression of pigeons. All the Saturdays in December have

is used even when the name is of Latin formation and therefore susceptible of infection.

PRIMULA SINOPURPUREA.

The members of the nivalis section of *Primula* have so far proved difficult of cultivation, being short lived and shy in flowering, but *P. sinopurpurea* (fig. 92) is a handsome species, which promises to be an exception to the rule. The plant is a native of Yunnan, China, and specimens were collected by Mr. George Forrest in open, moist, pasture land on mountains west

[Photograph by W. Irving]

FIG. 92.—PRIMULA SINOPURPUREA: FLOWERS ROSY-PURPLE.

been notified for organised pigeon shoots throughout Derbyshire, and advertisements to this effect have been issued by the County Committee.

THE COMMA IN BOTANICAL NAMES.—An interesting point is raised by Monsieur S. MOTTET in the *Revue Horticole* as to the desirability or otherwise of the comma in botanical names such as *Campanula patula*, Linn. Monsieur MOTTET follows the English practice of inserting the comma, but in this respect he differs from most Continental botanists, who hold that the signature, being in the genitive case, should follow the specific without the comma, which is superfluous and even misleading. In our own case, and in the *Index Kewensis*, the comma

of Fengkou at an altitude of 12,000 feet. The leathery leaves are dark green above, and coated beneath with a golden meal; they grow to a length of 12 inches, while the stems rise to a height of from 12 to 20 inches. The flower-stalk, like the under side of the leaves, is covered with a golden farina. In May the rich, rosy-purple, fragrant flowers are produced in trusses of 6 to 12 or more; each is about 1 inch in diameter, and has a grey "eye."

Kew is indebted to Mr. J. C. Williams for seeds of this *Primula*, which has grown vigorously, and promises to be easy to cultivate, flowering freely, and producing plenty of seeds. *P. sinopurpurea* grows best in a moist, partially-shaded situation, and in rich soil. W. I.

* *Journal Royal Agric. Society of England*, 77, 1915.

TREES AND SHRUBS.

FLOWERING SHRUBS IN WILTSHIRE.

The year 1917 has been remarkable for the wealth of bloom on all kinds of flowering trees and shrubs. The severe weather experienced in the early part of the year prevented any growth for some time, and afterwards there were no late frosts to do mischief. *Buddleias* flowered well, and the varieties of *B. variabilis* made a fine show. *B. asiatica* is pleasing, but it requires a wall to succeed here; *B. nivea*, too, with its woolly leaves, is very attractive. *Carpenteria californica*, although hit hard by the severe weather, flowered well; its large, Anemone-like flowers are very fine—here it is on a west border, and does well. *Clerodendron trichotomum* was superb; we have a fine bush of it, and its delightful perfume fills the garden. The Bladder Senna (*Coletea*) is very hardy and ornamental; *crenata* and *C. arborescens* both flowered well. *Cotoneasters* also make a good show; the berries and foliage at this date make a pleasing bit of colour, especially the creeping plants on the rockery, such as *adpressa* and *congesta*. The various *Cytisuses* (Broom) all did well, *Præcox* and *Andrusium* (Baisy Hill) especially. *Deutzias corymbiflora* and *kalmiflora* are both good, also the old *crenata* fl. pl., and all are very hardy. *Diervilla*, or *Weigela*, all flowered most profusely. The varieties *Abel Carrière* and *Eva Rathke* are both good; *Mont Blanc* is really very fine. *Eucryphia pinnatifida* is a treasure not often met with; its fine white flowers are freely produced, but it requires a somewhat sheltered position. The Spindle tree, *Enonymus empetrus*, is pretty just now; the pale red fruit and orange-flowered seeds are very attractive; this grows and flowers well in the shade of trees. *Forsythias* are very fine when planted in groups, and they are quite hardy; they need careful pruning after flowering. *Fremontia californica* is extremely handsome. There is a fine tree of it in the garden of the late Canon Ellacombe, at Bitton.

Hydrangeas all flowered well, especially in the south and west counties and near the coast. *Indigofera Gerardiana* is an uncommon and distinct shrub; here on a south border it flowers profusely, producing rosy-pink flowers in July and August—but it is very seldom seen in these parts. *Magnolias*; these are hardy and beautiful trees and shrubs, and flowering as they do in succession are very valuable. *Grandiflora* succeeds best on a wall, although it does fairly well as a shrub. *Conspicua*, *Lemnei*, *parviflora*, and *stellata* are all good. A fine North American species flowered well with us this year; it has immense leaves and fine white, fragrant flowers. Usually late spring frosts have spoilt many of the blooms. *Olearias*, although not really hardy in cold districts (with the exception of *Haastii*) are all valuable free-flowering shrubs. *Macrodonia* (very ornamental), with fine trusses of bloom, and *stellata*, are both good. *Nummularifolia* is very quaint and quite distinct. *O. insinuis* is very beautiful but only to be found in very favoured spots. One should always have spare plants of *Olearias*, especially in cold and damp situations. *Philadelphuses* have all flowered here with the greatest freedom. *Avalanche* was really superb, with its long, clean growths, wreathed with bloom, arching over most gracefully. *Pompet Blanc*, too, was exquisite; *Boule d'Argent* and *Fantaisie* were also very good, the latter a beautiful hybrid; these all need careful pruning after flowering. *Pittosporum Tobira* flowers well here on a south border. *P. crassifolium* and *P. undulatum* are both fine and fragrant. All kinds of *Prunus* flowered well, such as *Amagdalus*, *persica*, *Mume*, *triloba*, and *Pissardii*, the latter in this neighbourhood fruiting very freely. *Pseudo-*

cerasus and *Cerasus pendula* also did well. *Pyruses*, too, flowered freely, including the genera *Malus* and *Cydonia*, and have been followed with highly coloured fruits. *Robinia hispida*, although, strictly speaking, a tree, but kept here somewhat shrubby, is another beautiful flowering plant, its long racemes of rose-pink flowers, resembling a *Wistaria*, are charming; it requires a sheltered situation, as the wood is very brittle.

Of the shrubby *Spiræas*, *S. Aitchisonii*, with its fine flowers and red bark, was very fine; this somewhat resembles *S. Lindleyana*. Of *Syringa* (*Lilac*), the attractive and sweet-smelling flowers all bloomed very freely, and some are very beautiful. *Madame Lemoine*, pure white, is a great favourite, and all are good for early forcing. *Veronicas* are best for seaside and mild districts. *Salicifolia* does well here, also varieties of *Andersonii*. The lovely *Hulkiana* succeeds best on a wall, but I have seen it as a bush, and a fine sight it is. *V. carnosula glauca*, *Autumn Glory*, and *Chathamica* are all fine on the rockery. Unless it be in favoured spots a reserve of these should be kept; last winter played sad havoc with most varieties in this neighbourhood, and even in more sheltered and favoured spots. The well-known *Guedler Rose*, *Viburnum Opulus sterile*, flowered grandly, huge balls of purest white *Carlesii* and *macrocephalum* deserve a place in every garden; the latter sometimes needs a wall. *Pheacium*, too, is lovely, and fine for grouping; this is a Chinese species, as also is *thytiophyllum*, which is very attractive; the flowers are succeeded by fiery-red berries.

In order to have them at their best, careful attention must be paid to the pruning of all kinds of flowering shrubs; no haphazard methods will do; experience and close observation will soon teach one how and when to prune to obtain the best results. *R. H. Long, M.C., Sham House Gardens, Wiltshire.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

NATIONAL UNION OF ALLOTMENT HOLDERS.—I would esteem it a great favour if you would be so good as to give publicity to an alteration in the time limit fixed for the passing of the resolution by allotment societies on the question of security of tenure, which I issued some days ago, and which was announced in the Press. The date originally given for the receipt of these resolutions, which will be presented in bulk to the Board of Agriculture, was December 10, but it has been found that the time allowed for the passing of the resolution was too brief, and it has therefore been decided to extend the date to January 31. *D. Clotter, 8, Buckingham Street, London, W.C. 2.*

FRUITING TREES AND SHRUBS (see p. 226).—Mr. Beckett's note on the winter fruiting of trees and shrubs interested me. In the gardens at Abbotshury we have had this season an abnormal number of fruits on trees and shrubs that have fruited very sparsely in previous years. The various Crabs have produced fruits of extraordinary colour and in large numbers, and the members of the genera *Crataegus* and *Cotoneaster* have been equally good. Apart from *Cotoneaster frigidus*, of which we have many large trees at the present time laden with fruit, one of the showiest species is *S. Simonii*, and another very graceful species is *C. pinnosa*. Some of the *Viburnums* have also been laden with fruits, especially *Viburnum Opulus sterile*. Amongst Wilson's plants, *Lonicera Maackii*, omitted by Mr. Beckett, is still a magnificent sight. We have raised a number of plants of this *Hymenocle* from seed, and they are now about 14 feet high. At the time of writing they are like huge bushes of Red Currants. *Lonicera Koehneana* is also heavily laden with fruits, but the berries are not so brilliant in colour. *Skimmia* in variety are very full of berries, but probably the most striking plant is

Prunus capitata, syn. *Benthania fragifera*. All our plants of this species suffered severely during last winter, but they recovered, and now the fruits are colouring; the branches are being weighted down with the quantity. Some of our plants are 25 to 30 feet high, so the effect can well be imagined. A large plant of *Rhaphi- prunus cyanocarpus*, probably 30 to 35 feet high and 20 feet across, has been very striking with its brilliantly coloured purple fruits, but, strange to say, a plant of *Stranvaesia glaucescens*, over 30 feet high, although it flowered freely, has never yet set any fruits. When in flower the tree is a magnificent picture. *Rhamnus Alaternus argenteus* has fruited more than usual this year, and with its bright coral fruits amidst its pretty, variegated foliage, is very striking. *Ruscus croceus* also has fruited more than usual this season, and the same remark is true of *Ruscus aculeatus*. One of the most striking plants in the gardens, when its foliage was a very deep copper, was a large plant of *Lagerstromia indica*, about 25 feet high and nearly 20 feet across. The tree did not flower freely this year, having produced only about 50 spikes of bloom, but, seen in the afternoon's sun, its foliage was magnificent. *Laurus nobilis* has fruited freely, also various species of *Prunus*, such as *P. pissardii*, which has never fruited freely in previous years. We also had a heavy crop of fruit on a small "Mirabelle" Plum. The fruits were delicious. Apart from fruits, this is an extraordinary season. At the time of writing (December 10) I have picked flowers of *Narcissus*, *Rhododendron*, *Acacia nerifolia*, *Camellia*, *Chionodoxa fragrans*, *Polyanthus*, *Wallflower*, *Berberis hyemalis*, *Roses*, and many others. *H. Empshall, Abbotshury, Dorsetshire.*

PLANTING RHODODENDRONS (see pp. 212 and 233).—With regard to Mr. Cook's note on the planting of *Rhododendrons*, I am quite aware that some growers believe that autumn planting is the best. A prominent characteristic of *Rhododendrons* is the densely fibrous nature of their roots, they always lift with a good ball of earth, and consequently can be transplanted with very little risk about mid-April. If the plants are well supplied with water after planting they are little affected by disturbance. There is a widespread belief that peat in the soil is necessary for the successful cultivation of *Rhododendrons*. This opinion would be dispelled if note were taken how well they flourish in a good, open, moderately moist loam. The plants will, of course, do well in peat, where the situation is not too dry, but not better than in rich, open loam. There is, therefore, no need to go to the expense of taking out a considerable depth of soil and replacing it by peat in order to make the staple suitable for *Rhododendrons*. Staff, clayey soils are unsuitable, also soils containing lime, hence it is useless to look for any measure of success in gardens where chalk abounds. *Rhododendrons* are greatly benefited by a top dressing in early spring, and especially where the soil is at all dry. A suitable material for the purpose consists of leaf-mould, mixed with a little loam and well decayed manure. Permanent planting is, in my experience, however, best done in April. *Rhododendrons*, as a rule, seed very freely, and this has a decidedly weakening effect on the plants, hence, in the case of choice varieties at least, the old flower-buds should be cut off as soon as their beauty is over. *James I. Paine, Aldham Vicarage Gardens, Wulford, Herts.*

THE EFFECT OF ONE PLANT ON ANOTHER.—My experience in planting Cabbages on old Strawberry beds is the reverse of that of J. V. I have for years adopted the following practice when doing away with Strawberry beds: As soon as the Strawberries are finished the plants are grubbed in and allowed to lie for a day or more according to the weather, then they are buried, together with the litter, and the ashes spread over the soil. No manure is applied, but just before planting the Cabbages lime is spread and tamped in. I have never had a failure with Cabbages grown in this way. Again, when making a new bed of Strawberries, setting the plants at 2 feet apart, I put Cabbages between

the rows, and these are pulled before the Strawberries need all the space. Old Strawberry beds are harbours of injurious insects, and there are other factors that may lead to failure, and such as bad weather and soil qualities, and I think that A. N. should look for something beside "toxin" if he would know the true cause of his ill-success. C. E. Bridgett, *Red Roots Gardens, Bloom Road, Teddington.*

SOCIETIES.

**ROYAL HORTICULTURAL
Scientific Committee.**

DECEMBER 4.—*President:* Mr. E. A. Bowles, M.A. (in the chair), Messrs. J. Hudson, J. Fraser, W. C. Worsdell, J. Odell, H. E. Lawson, and F. J. Chittenden (hon. sec.).

Calystegia sepium rosea.—Mr. J. Fraser showed specimens of the pink form of *C. sepium* which he had collected in apparently wild localities in Surrey. Possibly the seed was carried by some means from a garden; for the variety is often seen in gardens.

Convolvulus arvensis hastatus.—He also showed a curious form of the common Bindweed with very narrow leaves which he had found near Molesey, and it was found to agree with the description of the variety *hastatus*.

Hemerocallis.—Mr. Hudson showed a sample of finely powdered house refuse which was being offered as a manure. Since such samples contain large quantities of coal ashes it is unlikely that their value will be great, though if it is to be had for a nominal sum and at small cost for carting the material may be worth using. It is found to be somewhat variable in composition.

Supposed influence of light on fasciation and flower production.—Col. H. E. Rawson showed further illustrations of fasciation appearing in plants of *Topopolium tuberosum* which were screened in the open garden. Successive corolla had bifurcated till the stem, 22 in number, had become fasciated flat ribbons 10 to 21 mm wide, closely covered with leaves and without any flowers. In the same position for the two previous years and unscreened the plant showed no signs of fasciation and bore flowers freely.

Influences.—Further examples were shown of increased flowering arising on selectively screened plants: all leaves being sun-dried and the flowers appearing in clusters. Spontaneous examination had shown that red light had been in excess during the increased flowering and blue light during fasciation.

Seedling Pears with adventitious roots.—Mr. Bowles showed a seedling of *Pyrus Niedtzkyana* with adventitious roots in considerable numbers appearing at the nodes as in the old Burbank Apple, and as happens in seedling Orbits at times.

Chimonanthus fragrans.—Mr. Bowles also showed flowers of the variety *grandiflora* of *Chimonanthus fragrans* appearing thus early in the winter.

Staurtia Pseudo-camellia fruiting.—Rev. W. Wilks sent ripe fruits of *Staurtia Pseudo-camellia* from his garden, where, for the first time, fruits had been produced abundantly.

TRIAL OF SPRING SOWN BEET

The following awards have been made by the Royal Horticultural Society after trial at Wisley:

BEETS.

FIRST CLASS CERTIFICATE. No. 41, *Green Top*, sent by Sutton and Sons.

AWARDS OF MERIT. No. 47, *Bradford's Exhibition*, sent by Barr and Sons; No. 45, *Chelton's New Green Top*, sent by Scheibman, Ltd.; Nos. 36 and 37, *Dunlop's Nutting's Red*, sent by Barr and Sons and Nutting and Sons; No. 33, *Earl's Cur Garden Compact Top*, sent by Barr and Sons, but considered identical with Nos. 36 and 37; No. 49, *Sutton's Perfection*, sent, raised, and introduced by Sutton and Sons; No. 53, *Nutting's Selected Red*, sent by Nutting and Sons.

HIGHLY COMMENDED. — Nos. 67, 68, and 69, *Deep Blood Red Non-bleeding*, sent by McLennan, R. Veitch and Sons; D. Bell (raised and introduced by D. Bell); No. 65, *Sutton's Black*, sent by Sutton and Sons; No. 66, *Dobbie's Purple*, sent by Dobbie and Co. (the Committee consider 65 and 66 to be identical); No. 48, *Market Favorite*, sent, raised, and introduced by Sutton and Sons; No. 29, *Veitch's Intermediate*, sent by Sutton and Sons; No. 73, *Yates' Nonpareil Red*, sent by Barr and Sons, raised by Yates.

COMMENDED. — No. 51, *Carter's Perfection*, sent, raised, and introduced by J. Carter and Co.; No. 52, *Pragnell's Exhibition*, sent by Barr and Sons; No. 25, *Queen of the Blacks*, sent by Barr and Sons.

POTATOS.

The following awards were made to Potatoes resistant to wart disease, grown at Wisley, to compare the cropping and cooking qualities. The names in brackets following the name of the variety are of those who presented the seed tubers, or from whom they were purchased. The "seed" was, in each case, grown in Scotland or Ireland.

AWARDS OF MERIT.—Nos. 50 and 51, *Golden Wonder* (Dobbie and Co., Sutton and Sons); Nos. 6, 7 and 8, *Great Scot* (Dobbie and Co., Sutton and Sons, R. Veitch and Son) (the Committee consider that No. 9, *St. Douglas King* (Sands), and No. 10, *Southampton Wonder* (Togood and Sons), are identical with Great Scot); No. 20, *King Albert* (Sands); No. 5, *King George* (Sutton and Sons); Nos. 27 and 23, *Langworthy* (Dobbie and Co., Sutton and Sons) (the Committee consider No. 29, *Walter's Wonder* (Sutton and Sons) to be identical with Langworthy).

HIGHLY COMMENDED. — No. 26, *Burroughs Early* (Dobbie and Co.); No. 4, *Comquest* (Sutton and Sons); No. 45, *Dominion* (Dobbie and Co.); Nos. 15 and 14, *Favourite* (Dobbie and Co., Sutton and Sons); Nos. 32 and 35, *Rob Roy* (McAlister, R. Veitch and Son); No. 44, *St. Malo Kidney* (Fidler); No. 22, *The Crofter* (Dobbie and Co.); No. 24, *Twentieth Century* (Sutton and Sons); Nos. 42 and 43, *White City* (Dobbie and Co., Sutton and Sons); No. 49, *Western Hero* (R. Veitch and Son). The last variety has not yet been grown in the trials carried out under the Board of Agriculture for wart resistance.

SOUTHAMPTON ROYAL HORTICULTURAL.

At a recent meeting of the Council of the above Society Mr. C. S. Furdie, who will complete 45 years' continuous service as secretary at the end of this year, and is in his 72nd year, tendered his resignation. The Council, however, induced him to continue in office, with the help of an assistant secretary, and Mr. J. T. Robb was appointed to the latter position.

The annual statement of accounts for the twelve months ending November 30 showed a credit balance of over £134.

It was decided to hold, next year, a Rose Show at South Stoneham House grounds, on June 20, and the Summer Show, on the Pier, on July 25 and 24.

It was also decided to hold a fruit and vegetable show to encourage food production, with special classes for allotment cultivators, on October 15 and 16.

Obituary.

JAMES E. HOPE.—We regret to record the death, from acute pneumonia, on December 8, of Mr. James Edward Hope, of Belmont, Walsingham. Mr. Hope was nearly related to the late Miss Hope, of Wardie Lodge, Edinburgh, and, like her, was a keen horticulturist. He was specially interested in Alpine and hardy flowers, and had one of the best-kept gardens in the Edinburgh district. Deceased, who was born in 1852, was formerly in charge of the Estate Duty (Scotland) Office.

CROPS AND STOCK ON THE HOME FARM.

WHEAT IN 1918.

The extremely dry weather experienced during the whole of November and the latter part of October was almost a record for that period of the year, very different from that experienced in October and November, 1916, when only twenty-five dry days were recorded for the two months, and the sowing of Wheat was in consequence much hindered. The present season has been quite ideal for this work, and there have been a few sharp frosts to disintegrate tenacious clods and make harrowing all the easier. In spite of what was thought to be a bad harvest season for seed Wheat, the plant, now well established and giving through the soil, is very strong, and gives promise of satisfactory growth later. Indeed, it is admitted generally that Wheat never looked better than it does at the present time. The favourable weather, too, is encouraging an extended seeding season. Most acres will be sown than would have been the case had the weather been unfavourable. Rocks have been less troublesome than usual, and this is indeed a boon in these days of labour shortage.

I find a tendency this season amongst farmers to make use of the newer varieties of Wheat, especially those that produce heavier yields, if not of quite such high quality. No doubt this is wise when it is considered that quantity is the main object to study at present.

It is pleasing, too, to note that there is a greater desire to sow seed that has been well prepared, by screening the smaller and inferior grains from the bulk, thus starting with a uniform sample of seed.

Much grass-land and old leys have been ploughed and sown with Wheat in the general wish to produce an increased crop. Where a prepared wheat manure was sown along with the Wheat the plant is promising in growth and colour alike. With a dressing of sulphate of ammonia in February at the rate of 1 cwt. per acre these by-sown Wheats should produce satisfactory results.

No doubt there are still many plots yet to sow, where the previous crop is Rape and Turnips to be fed off by the sheep. If a difficulty is found in working the soil into a satisfactory tilth, and to save time, it is a good plan to sow the seed first and plough it in, harrowing the surface afterwards. In the case of "catchy" weather this is a good plan if only a small portion is sown daily. On thin soils a covering chalk it is a good plan to use a heavy pressure to aid in solidifying the soil, as Wheat likes a firm rooting medium, and especially is this an advantage where rocks abound.

Fallows that were ploughed up out of stubble after harvest and intended for Swedes and Turnips should be cross-ploughed when the weather is suitable. In no circumstances should stiff fallows be broken upon when wet, as that only brings trouble later on when a fine surface tilth is required.

Owing to strong winds, much rain, and in many cases heavy ears of grain, Oads were badly laid last autumn, and there was much "busted" Corn, which is now growing freely. The dis-turbing of the fallows now will destroy these self-sown plants and check the growth of weeds, including Dock, which may easily be collected after the plough and burnt. I notice that there are increasing numbers of this weed, especially in arable fields. The Docks may be due to Hay fed to sheep on the land, neglect to take the weeds out of the previous Corn crop, and by carting out manure where Hay was fed to cattle in the yard. Any stubble intended for roots and not yet ploughed should be attended to without delay. This is the time to plough the land an extra inch or two deep for this crop, especially if the soil is heavy and the sub-soil somewhat pervious to water. All subsequent ploughings should be less deep, as Turnips appreciate a firm rooting medium. The first or second ploughings will aid in pulverising the surface soil by exposure; too fine a seed bed is not possible for roots, therefore any help

given in that direction now will be valuable later on.

MANGOLD.

The present is a good time to cart manure on the land for this crop. The dung should be ploughed in at once to ensure it being thoroughly decayed and integrated with the soil by late June sowing is done in April. With the use of 15 to 20 tons per acre of half-decayed manure, ploughed in in the autumn, and 4 cwt. of superphosphate per acre at sowing time, excellent crops may be obtained without the aid of further stimulants in the form of nitrate of soda or sulphate of ammonia.

Again, good Mangolds are obtained by the aid of artificial manure only. Where farmyard manure is scarce or required for other crops no one need despair of growing good Mangolds. I had fully 35 to 40 tons per acre on one 6-acre plot enriched with 4 cwt. of superphosphate and 8 cwt. of agricultural salt per acre; not a scrap of any ammonia stimulant was used. A good tilth, early sowing, and keeping the land clean, are the essentials to success. The superphosphate was not drilled with the seed, as is commonly done, but sown broadcast in front of the drill and worked in by the harrows when preparing the seed-bed.

CARROTS.

The crops of both Red and White Carrots have been remarkably good this season where the land was thoroughly prepared and the attention given the plants in their early stages of growth in keeping them free from weeds. Carrots, apart from their value for feeding purposes, are a remunerative crop.

Now is the time to prepare the land by extra deep ploughing to ensure a free rooting medium, as good Carrots cannot be grown in shallow soil. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham, Hants.*

ANSWERS TO CORRESPONDENTS.

APPLE, PEAR AND PLUM TREES FRUITING UNSATISFACTORILY: *D. G. S.* Give the cordon Pear, bush and standard Apple trees, the dressing of basic slag now. Trees of the age you mention would benefit most from a good dressing of farmyard manure if available, or they could be mulched with this material in the spring. The same remarks apply to the Plum trees you are dressing with lime. The Apples also would be benefited by a dressing of lime.

ASPIDSTRAS: *C. M.* Mix a little bone-meal with the potting soil and water the plants occasionally with a weak solution of some nitrogenous fertiliser, such as sulphate of ammonia or nitrate of potash. If you wish for a complete fertiliser use Touk's manure, which is made as follows:—

Superphosphate	12 parts.
Nitrate of Potash	10 parts.
Sulphate of Magnesia	2 parts.
Sulphate of Iron	1 part.
Sulphate of Lime (Gypsum) ..	8 parts.

CLIMBERS FOR A NORTH-EAST ASPECT: *J. C. B.* Suitable sweet-scented climbers for a low, north-east wall are *Chimonanthus fragrans*, *Choisya ternata*, *Lonicera aurea reticulata*, *L. fragrantissima*, and *Philadelphus* *Monster*. The following Roses will also do well in such a situation: *Comon China*, *Gross* an *Tepitz*, *Reine Marie Henriette*, *Rève d'Or*, and all the members of *Gloire de Dijon* class. Other useful plants, although not scented, are *Clematis*, *Cotoneaster*, *Jasminum nudiflorum*, and *J. officinale*.

CROSEOTE FOR SPRAYING: *C. L.* The croseote would probably be less effective than the ordinary caustic washes at present used for winter spraying. At the same time, if the trees are not badly affected by pests, and are free from Lichens and Moss, the croseote or insecticide would probably meet the case very well. In general, the good effect of any of these washes is due primarily to their cleansing properties. Croseote, if used strong, is fairly caustic, and must be handled with care.

GARDENER'S NOTICE: *C. C.* It is usual for a gardener living in a house on his master's property to give or to receive a month's notice before leaving his situation. The agreement you made with your employer at the time of the appointment should have been committed to paper; a verbal agreement is useless. We note the reason you state for your discharge; this fact, if correct, may make all the difference in regard to the amount of notice required. You should consult a local solicitor.

NAMES OF FRUITS:—In the naming of fruits, we desire to oblige our correspondents as far as we can, but the task would become too costly and too time-consuming were there no restrictions. Correspondents should observe the rule that NOT MORE THAN SIX VARIETIES be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. The fruits should be just approaching ripeness, and they should be properly numbered, and carefully packed in strong boxes; cardboard is often smashed in the post. A leaf or shoot of each variety is helpful, and in the case of Plums, Prunes and Nectarines, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. By neglecting these precautions, correspondents add greatly to our labour and run the risk of increased delay and incorrect determination. We do not undertake to send answers through the post, or to return fruits. Fruits and flowering plants must not be sent in the same box. Delay in any case is unavoidable.

W. A., Bristol. Doyenné du Comice.—*W. D. and Sons.* Fondante d'Automne.—*E. P.* Reineette Franche.—*A. T. H.* 1, Hornmead Peppermint; 2, Striped Beefing; 5, Small's Admirable; 4, not recognised; 5, Old Nonpareil.—*A. R. P., Wandle.* 1, Franklin's Golden Pippin; 2, Gascoyne's Scarlet Seedling; 3, Alfriston; 4, Flower of Kent; 5, Doyenné du Comice; 6, Uvedale St. Germain's.—*R. C. W.* Pear Beurré Clairgeau; Apple Beauty of Kent.—*J. G. D.* 1, Dumelow's Seedling; 2, Annie Elizabeth; 3, Sturmer Pippin; 4, Wyken Pippin; 5, not recognised; 6, Joséphine de Malines.—*G. B., Cranleigh.* 1, Golden Russet; 2, Lady Henrick; 3, Hambleton Deux Ans.—*S. R.* 1, Bacon's Incomparable; 2, Marie Louise; 3 and 4, decayed; 5, Dumelow's Seedling (syn. Wellington); 6, not recognised.—*R. W. R.* One large Pear, Beurré Diel; two Pears, Soldat Labourer.—*Christian.* 1, Round Winter Noneseuch; 2, Wyken Pippin; 3, Triomphe de Joazeux.—*P. M.* 1, Striped Beefing; 2, The Queen; 3, Golden Harvey; 4, Reineette van Mons; 5, Northern Spy.—*R. M.* 1, Rosemary Russet; 2, Cockle Pippin; 3, not recognised; 4, Reineette du Caux; 5, and 6, decayed.—*I. S.* Apple Castle Major.—*Triton.* 1, Ponsard's Noneseuch; 2, Norfolk Beefing; 3, Golden Spire; 4, Norfolk Stone Pippin.—*D. W.* Green Winter Greening; flushed, Api Rose.—*W. O. A.* 1, Nanny; 2, Reineette du Caux; 3, Dumelow's Seedling (syn. Wellington); 4, not found; 5, Golden Pippin.—*I. E. H.* 1, Pear decayed; 2, local, not recognised; 3 and 4, Hanwell Sounding; 5, Wormsley Pippin; 6, York-shire Beauty.—*J. C.* 1, Triomphe de Joazeux; 2, White Doyenné; 3, Van Mons Léon Ledere; 4, Joséphine de Malines; Apple Pine Golden Pippin.—*E. B. P.* 1, King of the Pippins; 2, Lady's Finger; 3, Hanwell Sounding.

NAMES OF PLANTS:—Correspondents not answered in this issue are requested to be so good as to consult the following number.

J. O., Reading. *Juniperus communis fastigiata*, the Irish Juniper.—*F. S. M., Wrexham.* The flower sent is a *Cattleya labiata* of the autumn-flowering type. *C. labiata* is a very variable species, both in the form and tint of its flowers, the shape of its pseudo-bulbs and width of the leaves. There is little doubt that the other one described by you is of the same species. Send specimens of the other Orchids as they bloom, for naming.—*F. W. J.* *Linaria Cymbalaria*, Ivy Toad Flax.

PEARS SPOTTED: *J. E. H.* There is no fungus present on either of the Pears, and the injury appears to be only superficial. Spray the trees in the spring, when the leaves are just opening, two or three times, at intervals of a few days, with weak Bordeaux mixture.

PLANT "FIXTURES": *T. B.* Plants which are growing in the soil are part of the freehold

and belong to the landlord. Consequently they cannot be removed by an outgoing tenant. There is not any legal decision reported to the effect that a tenant has any right to remove plants which are necessarily placed in the soil temporarily with a view to replanting, although we may expect to find, sooner or later, a test case fought out, in which the tenant will plead "custom" to that effect. Plants standing in pots or growing in a detachable window-box have been held to be removable by the tenant, but there are cases reported in which it has been held that hedges, plants, and a border of Box formed of such plants cannot be so removed. These cases apply to a private garden only; the nurseryman, for instance, has the right to remove growing plants from the soil, as this right is a necessary incident to his business by reason of its special nature.

PRUNING RHODODENDRONS: *T. Clewlow.* Rhododendrons and similar hardy shrubs should be pruned in early spring before growth commences. *Rhododendrons*, by W. Watson, deals with the pruning and propagation of these flowering shrubs. You can obtain the book from our publishing department, price 1s. 10d., post free.

RAISING ORCHIDS FROM SEEDS: *W. W.* Orchids have both the male and female organs in the same flower. The pollen is found in a mass known as pollinia, at the apex of the column. When the flowers are ripe it is usually possible to withdraw the pollinia by means of a pointed stick, and it should be transferred to the stigma of the plant intended to be the seed-bearer. You will find information on the crossing and raising of new Orchids in *Orchids*, Present-Day Gardening Series, obtainable from our Publishing Department, price 1s. 10d., free by post.

RAISING VEGETABLE SEEDS: *D. H. S.* We know of no work dealing exclusively with the raising of vegetable seeds, but any good cultivator of vegetables would be able to inform you as to the planting of specimens desired for seedling purposes.

TIMBER: *E. H. B.* A good work on timber is *Wood*, by Prof. G. S. Boulger, published by Edward Arnold, London, 1903, price 12s. 6d. The following are the names asked for: *Padouk* (*Pterocarpus indicus*), *Saunwood* (*Chloroxylon Swietenia*), *Rio Rosewood* (*Dalbergia nigra*) *Sri Lanka*, *Borneo Rosewood* (*Pterocarpus* sp.), *Cunary Wood* (*Liriodendron Tulipifera*), *Pitch Pine* (*Pinus australis*), *Yellow Pine* (*Pinus mitis* and *P. ponderosa*), *Red Deal* (*Pinus sylvestris*), *Cedarwood*. There are over 60 different Cedarwoods, and we do not know which one is meant. *Silver Gray* *Sycamore* is not known to us.

VEGETABLES UNDER GLASS: *Catherine.* You are right in assuming that every possible use should be made of glasshouses for the production of early vegetables. To advise you how to apportion the space available we should require to know the requirements of the household as to any particular vegetable. Assuming an average demand, one-half should be devoted to early Potatoes, such as *Midlothian Early* and *May Queen*; one-quarter to Peas and climbing French Beans, and the rest divided between early Turnips, Carrots, Cauliflowers, and various kinds of salads. The soil of the cultivated ground on which the glasshouses are to be erected will, if of good quality, be suitable for the purpose of growing vegetables.

YOUNG ESPALIER APPLE TREES: *W. L. W.* Generally speaking, it is necessary to reduce the extension shoots of espalier Apple trees about one-third their length. All the side shoots should be pinched back to two or three leaves during the summer, the leaders only being allowed to grow their full length throughout the season, shortening them as recommended above at the winter pruning.

Communications Received.—*W. E., H. A., G. F., R. W., R. E., H., J. S., E. S., M., F. T., A. R., E. C. W., T., W. O., W. E., E. H. A., O. P., Ignorance.*—*H. G., W. B. H., O. T.*

MARKETS.

COVENT GARDEN, December 12.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing plants in pots such as Aralia Sieboldii, Asparagus plumosus, and Begonias, with prices in s.d. and s.s.d.

Cut Flowers, &c.: Average Wholesale Prices.

Table listing cut flowers such as Arums, Begonias, and Camellias, with prices in s.d. and s.s.d.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing cut foliage such as Adiantum (Maiden hair Fern) and Asparagus plumosus.

REMARKS.—Supplies consist chiefly of those already given for the Christmas trade. The cold weather has checked the supply of Roses and Carnations, and the prices for these flowers are advancing, and will doubtless continue to rise throughout next week. Business is very brisk in the present prices. Ferns are only of medium quality, but they are selling freely at advanced prices.

Vegetables: Average Wholesale Prices.

Table listing vegetables such as Artichoke, Asparagus, Beans, Beetroot, Brussels Sprouts, Cabbage, Carrots, Cauliflowers, Celery, Cucumbers, Endive, Garlic, Greens, Herbs, and Watercress.

Fruit: Average Wholesale Prices.

Table listing fruits such as Almonds, Apples, Apricots, Raspberries, Grapes, Almonds, Apples, Apricots, Raspberries, Grapes, Almonds, Apples, Apricots, Raspberries, Grapes.

REMARKS.—The market is well supplied with Apples of seasonable varieties, but Pears are limited in numbers. The demand for grapes has not been so great during the past week as hitherto, and this may be due to the increased prices. The consignments of Grapes from the Channel Islands are practically finished. Oranges, Lemons, Nuts, Brazil-nuts, and Dates are all scarce and expensive. The Potato crop is finishing. Asparagus, both English and French grown, is on offer. Mushrooms are obtainable. Peas, Dwarf Beans, new Potatoes, Chickens, and Mint. All outdoor vegetables are plentiful.

GARDENING APPOINTMENTS.

Mr. D. H. Rose, for the past five years Gardener to B. N. SILEM, Esq., Cantley Manor, Norwich, as Gardener to E. H. KING, Esq., Summerfield, Dorking, King's Lynn. Mr. J. Mann, for the past ten years, Gardener to E. S. Low, Esq., Redley Park, Yoxford, Suffolk, and previously at Kilsbane, Tipperary, as Gardener to Mrs. BARNARD, Kirkington Hall, Kirklington, Southly, Northamptonshire. Mr. W. J. Newbery, formerly of the Royal Botanic Gardens, Kew, and the Royal Botanic Society's Gardens, Regent's Park, London, and for the past seven years, Chairman of the Board of Gardens, Peterborough, Notts, as Superintendent of Public Parks to the Peterborough Municipality.

AUCUBA JAPONICA.

RHODODENDRON PONTICUM. RHODODENDRON PINK PEARL. (Fines Named Hybrids.)

All the above 2ft. to 4ft. bushy, good plants for Covent Planting. Must be sold cheap, to make room for potatoes. If not disposed of must be burned.—A BARGAIN!

Particulars from R. MANSON, Nurseryman, Gateacre LIVERPOOL.

Do Not Forget the Gardeners-Soldiers.

"Many thanks for the GARDENERS' CHRONICLE, which I have received safely each week through the kindness of Lady Theodora Guest. You will see that I am now in Mesopotamia. The CHRONICLE is very welcome to me out here; it seems good to read all the news in the old paper, and surely the GARDENERS' CHRONICLE is the king of all gardening papers."

This letter was sent us by a soldier in the Mesopotamia Force. YOUR soldier friend, who was a gardener before he went to the front, is a gardener still in sympathies and interests. HE longs to know what is going on in the gardening world now, and has no means of knowing unless YOU help him. Send him the GARDENERS' CHRONICLE. Keep him in touch with current gardening affairs. He will be most grateful for such an act of friendship. Send us a subscription for half-a-year —8/9—and we will take all the responsibility of sending the paper regularly to your friend, also reminding you punctually if the subscription is about to expire.

Write to us now, and give us his address. 41, WELLINGTON ST., STRAND, LONDON, W.C. 2

The Best Christmas Present.

The following volumes of

PRESENT-DAY GARDENING

Edited by R. HOOPER PEARSON, Managing Editor, "Gardeners' Chronicle."

EACH VOLUME IS WRITTEN BY AN EXPERT. ILLUSTRATED WITH EIGHT PLATES REPRODUCED FROM COLOUR PHOTOGRAPHS. ❁ ❁

THERE is no more delightful occupation for the long evenings of winter than reading. To make up a good fire, and take in one's hand a favourite book, this represents the same of comfort over a hard day's work. In reading, as in everything else, it is "everyone to his taste", and the garden enthusiast, be he professional or amateur, will choose for his winter evenings a book which deals with the subject nearest to his heart (that of horticulture). And on this theme, old yet ever new, no volume can give so much and so varied information within such a compact as a bound volume of the "Gardeners' Chronicle". On one page it tells of the latest discovery in horticultural science, and describes the rich harvest of new plants introduced into cultivation by intrepid plant collectors from the remotest parts of China and Tibet. On another page it relates the progress of the horticulturists of today in the raising of new plants by hybridizing, and, again, it tells the romantic history of the latest variety in the domain of plant life. The "Gardeners' Chronicle" has been printing such records for over seventy years.

FERN'S FERN'S!—Tree Ferns, Climbing Ferns, Basket Ferns, Stove and Greenhouse Ferns, 1143 Garden Ferns, catalogues free. **J. T. SMITH, London Fern Nurseries, Loughborough Junction, London, S.W.**

Books as Christmas Presents.

There is nothing so helpful to a young gardener as carefully selected books written by successful cultivators in the various branches of gardening.

- Botany, A Year's.** Adapted to Home and School Use. By Frances A. Kitchener. With 195 Illustrations. 8s. 4d.
- China, A Naturalist in Western.** By Ernest Henry Wilson. Illustrated, in Two Volumes. £1 10s. 6d.
- Flora, British, Handbook of the.** By Geo. Bentham. Revised by Sir Joseph Hooker. Seventh Edition. 9s. 5d.
- Fertilisers and Manures.** By A. D. Hall, F.R.S. 5s. 5d.
- Garden, Chemistry of the.** A Primer for Amateurs and Young Gardeners. By Herbert H. Conson, M.A. 1s. 5d.
- Garden Craft in Europe.** By H. Inigo Triggs. £1 15s. 6d.
- Insect and Allied Pests of Orchard, Bush and Hothouse Fruits.** By F. V. Theobald, M.A., etc. 32s Illustrations. 50s. 6d.
- Insects, Injurious and Useful.** An Introduction to the Study of Economic Entomology. By L. C. Miall, F.R.S. 140 Illustrations. 5s. 9d.
- Intensive Culture of Vegetables on the French System.** By P. Aquinas. Illustrated 4s. 5d.
- Johnson's Gardener's Dictionary.** New Edition. 9s. 6d.
- Judging, Rules for.** Issued by the Royal Horticultural Society. Latest Edition. 1s. 6d.
- Landscape Architecture, The Art of.** By Samuel Parsons. A practical and authoritative work. Illustrated. 12s. 6d.
- Lawns.** By Sutton and Sons. Reading. In paper cover. Well illustrated. 1s. 3d.
- Lawns and Greens.** By T. W. Sanders. A Guide to the Formation and Management of Lawns, Tennis Courts, etc. Illustrated Paper. 1s. 10d.
- Lily, Book of the.** By W. Goldring. Illustrated 2s. 9d.
- Little Gardens and How to Make the Most of Them.** By H. H. Thomas. A handy and useful work for the Amateur. Paper. 1s. 3d.; cloth. 1s. 9d.
- Mango, The.** By G. Marshall Woodrow. An account of its Culture and Varieties. 1s. 1d.
- Manures and the Principles of Manuring.** By C. M. Aikman. 6s. 10d.
- Manures for Garden and Farm Crops.** By W. Dyke. Cloth. 1s. 9d.
- Manuring, The Science and Practice of.** By W. Dyke, with introduction by J. Wright. A most practical work for the Amateur, Market and Professional Gardener. 1s. 2d.
- Manuring of Market Garden Crops, The.** By Bernard Dyer and F. W. L. Shrivell. New Edition. 1s. 5d.
- Mendelism.** By R. C. Punnett, F.R.S. New and Enlarged Edition. 5s. 4d.
- Mendel's Principles of Heredity.** By W. Bateson, F.R.S. 12s. 6d.
- Mushrooms, and How to Grow Them.** By John F. Barter. An excellent Treatise. Illustrated. 1s. 2d.
- My Garden in Spring.** By E. A. Bowles, M.A., Chairman of Scientific Committee of Royal Horticultural Society. With Preface by Reginald Farrer. "Mr. Bowles . . . has the time to be his own gardener, and has thereby gained that first hand knowledge of plants without which any writer on horticultural subjects is . . . apt to be neither interesting nor informing." Price 5s. 6d.
- My Garden in Summer.** By the same author. Price 6s. 6d.
- My Garden in Autumn and Winter.** By the same author. 5s. 6d.
- Orchids and their Cultivation.** By James O'Brien, V.M.H., Hon. Sec. of the R.H.S. Orchid Committee. Contains 3 full page Coloured Plates from colour photography. 1s. 10d.
- Orchids: Their Culture and Management.** By W. Watson. Curator, Royal Botanic Gardens, Kew, and H. J. Chapman. Illustrated with 139 Engravings and 20 Coloured Plates. 25s. 9d.
- Orchids, Fertilisation of.** By Chas. Darwin. Illustrated. 3s. 11d.
- Orchid Grower's Manual, The.** By the late B. S. Williams. 60 pages. Numerous Illustrations. 10s. 6d.
- Pansies, Violas and Violets.** By W. Cathbertson and R. Hooper Pearson. With 3 full page Coloured Plates from colour photography. 1s. 10d.
- Pansies and Violets.** By D. B. Crane. Paper. 1s. 2d.; cloth. 1s. 9d.
- Peach, The Book of the.** By H. W. Ward. A Practical Handbook on the Cultivation of Peaches and Nectarines under Glass and Out of doors. 2s. 10d.
- Pears and Plums, The Book of.** By the Rev. E. Barrum, D.D. Illustrated. 2s. 9d.
- Pinus, The Genus.** By George Russell Shaw. Price £2 15s. 6d.
- Plant Breeding.** Being Five Lectures upon the Amelioration of Domestic Plants. By Prof. L. H. Bailey. Illustrated. 6s. 11d.
- Plant Life.** By C. A. Hall. £1 6s. 6d.
- Practical Plant Physiology.** By Frederick Keeble, F.R.S. Illustrated. 5s. 10d.
- Practical Tree Repair.** By Elbert Peets. The Physical Repair of Trees—Bracing and the Treatment of Wounds and Cavities. Illustrated. 7s. 11d.
- Plants and Trees, Diseases of Cultivated.** By George Masson. Well Illustrated. 7s. 11d.
- Plants, A Popular Treatise on the Physiology of.** By Dr. Paul Saranar. Translated by F. E. Weiss, D.Sc. With 33 Illustrations. 9s. 6d.
- Primula, Handbook of the Hardy.** By H. M. Paul. An Illustrated Work on the Culture, Mode of Growth and Utility of Primulas. 1s. 14d.
- Pruning, The Handy Book of.** With Chapters on Grafting and Budding. By James Udale, with introduction by the Right Hon. Viscount Cobham. New Edition. Illustrated. 1s. 9d.
- Rhododendrons and Azaleas.** By W. Watson. With preface by Sir. F. W. Moore, F.L.S. (The first popular volume published on this subject.) 3 full page Coloured Plates. 1s. 10d.
- Rock Gardens.** By Reginald Farrer. With Preface by Dr. J. Bretland Farmer, F.R.S. Contains 3 Coloured Plates. 1s. 10d.
- Rock Garden, The English.** By Reginald Farrer. A complete dictionary of Hardy Plants suitable for Rock Garden Culture. Contains 500,000 words and 500 Illustrations. In 2 Vols. Price, £2 2s. 10d. post free (in the press).
- Root and Stem Vegetables.** By the late Alexander Dean. Contains 8 full-page Coloured Plates. 1s. 10d.
- Rose, The Book of the.** By Rev. A. Foster Melliar, M.A. Illustrated. New Edition. 5s. 5d.
- Roses.** By H. R. Darlington. Contains 8 full-page Coloured Plates. 2s. 11d.

THE BOOK OF THE MOMENT.
Root & Stem Vegetables
By **ALEXANDER DEAN, V.M.H.**

At the present crisis the food problem bulks largely. The question of which vegetables contain the most food is a pressing one, and it is found that root and stem vegetables, such as Potatoes, Carrots, Turnips and Parsnips, contain much higher percentages of food value than green vegetables, valuable though these are as adjuncts.

"ROOT AND STEM VEGETABLES" is a book which treats only of those vegetables the root or stem of which is eaten, and is therefore especially valuable to all who are endeavouring to concentrate their attention on growing the most economical forms of food. It contains eight coloured plates reproduced from photographs.

ON THE BOTANY AND PHYSICAL GEOGRAPHY OF THE HOLY LAND.

OVER and above the botanical and their religious and historical associations, Palestine and Syria form one of the most wonderful regions in the world. The physical, climatic, and geological characters of the country are so varied that within a tract, with an area of 50,000 square miles, about the size of England or the State of New York, 3,500 species of plants, not going down lower in the scale than Ferns, have been already collected, and in all probability further exploration of the hills on the east side of the Jordan will raise the number to 4,000. The total number of species known in Great Britain is 1,500, and in the whole of Europe 10,000. The whole of the country west of the Jordan has now been well explored at different seasons of the year. A wealthy Swiss botanist who died long ago devoted his life to the study of the Oriental region and published a *Flora Orientalis* in five large volumes, in which he brought together the results of his own explorations, and the work that had been done by his predecessors. Founded upon this, Canon Tristram has drawn up, for the Palestine Exploration Society, a list of the plants of the Holy Land, and still more recently my friend, the late Dr. Post, who was for a long time connected

with the Syrian Protestant College at Beirut, published a flora of Syria and Palestine, in which all the genera and species are described. In the autumn of 1860, Sir J. D. Hooker, in company with the late Daniel Hanbury, paid a visit to the Holy Land and the former wrote for Smith's *Dictionary of the Bible* a general sketch of its botany. One of my latest official acts at Kew was to lay out a large and beautiful set of Palestinian plants gathered in 1897 by a botanist named Bormmuller. In the following notes all the sources of information have been drawn upon. Palestine in its botany combines in a remarkable manner the characters of the East and West. From a physical point of view we have a very remarkable and abnormal feature in the Jordan Valley and the Dead Sea, which form a trench deeply excavated below sea-level, so that if the hills were pierced from the head of the Plain of Esdraon, the waters of the Mediterranean would flow in and form a long, narrow lake like Tanganyika in Central Africa. There is a continuous trench that runs north and south parallel with the sea through 10° of latitude, from Antioch to the Gulf of Akaba. First it forms the Valley of the Orontes, then that of the Leontes, separating the Lebanon from the Anti Lebanon chain of mountains, where it reaches 3,600 feet. Then it descends deeply in the valley of the Jordan, so that the Lake of Tiberias is 680 feet and the D. of Sea 1,500 feet below the level of the Mediterranean. It is continued south along the Wady el Arabah, or the head of which it is a few hundred feet above sea level, and then sinks to the Gulf of Akaba, which forms a long arm of the Red Sea. Whilst the rest of Palestine has a climate like Greece and Italy, this excavation is more like Egypt and Arabia, and the vegetation varies accordingly. We may therefore in Syria and Palestine trace out four different zones of temperature, as follows, viz. —

I. THE SUB-TROPICAL REGION.

This includes the southern deserts and the Jordan Valley. A group of sub-tropical plants adapted to sandy soil and a climate with very little rain extends from Senegambia, through Egypt and Arabia, to the N.W. of India, and many of these which are entirely absent from Europe enter the Palestinian flora in this region. Sir J. D. Hooker writes: "No where can a better locality be found for showing the contrasts between the eastern and western districts of Syria than in the neighbourhood of Jerusalem. To the west and south of the city the valleys are full of the Dwarf Oak, two kinds of Pistacia, Smilax, Arbutus, Rose, Aleppo Pine, Rhamnus, Phyllyrea, Brundle, and Crataegus Aronia. For the first few miles the Olive groves continue, and here and there is a Carob and Lentix or Sycamore, but beyond Bethany they are scarcely seen. On descending 1,600 feet below the sea to the valley of the Jordan, the sub-tropical and desert vegetation of Arabia and West Asia is encountered in full force. Many plants wholly foreign to the Western

district suddenly appear, and the flora is that of the whole dry country as far east as the Punjab. The commonest plant is the Zizyphus Spina-Christi, forming bushes or small trees. Scarcely less abundant and as large is *Balanites aegyptiaca*, the fruit of which yields the oil called by the Arabs "Zuk," which is reputed to possess healing properties. Tamarisks are abundant. *Acacia Farnesiana* is very plentiful and celebrated for the delicious perfume of its yellow flowers. *Capparis spinosa*, the common Caper plant, flourishes everywhere in the Jordan Valley. *Alhagi maurorum* (a favourite food of the camel) is extremely common, as is the prickly *Solanum coagulans*, with purple flowers and globular yellow fruits, commonly known as Dead Sea Apples. On the banks of the Jordan itself the arborescent and shrubby vegetation chiefly consists of *Populus euphratica*, *Osyris alba*, *Periploca*, *Acacia*, *Prosopis*, *Lycium*, *Arundo Donax*, and *Capparis spinosa*. As the ground becomes saline, *Atriplex Halimus* and large *Statice* appear in vast abundance. Other tropical plants of this region are *Zygophyllum coccineum*, *Boerhaavia*, *Indigofera*, *Cassia*, *Gymnocarpum*, and *Nitraria*. In addition to the plants mentioned in the foregoing extract, I may add *Moringa aptera*, *Salvadora persica*, the Betam Broom, and two species of *Ephedra*, and amongst herbaceous types *Anastatica hierochuntica* (the Rose of Jericho), *Ergoniu cretica*, three species of *Mesembryanthemum*, two species of the allied genus *Aizoon*, *Ochradeus hincatus*, *Lippia nodiflora* (a prostrate Verbena), *Cnemis prophetarum* (Jonah's Gourd), *Diemia coriata*, several *Anemone* and members of the *Chenopodiaceae*. The stems of these plants are often prickly, and the flowers inconspicuous. Ferns are almost absent.

2. THE COAST PLAINS.

A tract of level ground 12 or 15 miles in breadth extends between the sea and the hills through Judaea and the southern half of Samaria. In the south it includes the ancient lands of the Philistines and in the north it is called the Plain of Sharon. At the north end of it the limestone promontory of Mount Carmel juts out into the sea with the village of Haifa beneath it on the north side. North of Mount Carmel the Plain of Esdraon extends for some distance inland, past Tyre and Sidon and Beirut, the hills come up close to the sea, but further north, past Tripoli and Latakia to Mount Cassius, there is a level plain, and also north of Mount Cassius from Antioch inland. The coast plains consist of rich, loamy soil, and are the most fertile portion of the Holy Land. The Philistine plain is described as follows (Smith's *Concise Dict. of Bible*, p. 671): "The whole plain appears to consist of loamy soil, light but rich, and almost without a stone. It is to the absence of stone that the disappearance of its ancient towns and villages is to be traced. It is now, as when the Philistines possessed it, one enormous cornfield; an ocean of Wheat covers the whole expanse between the hills and the

... of the ashore without interruption of ... break or hedges, hardly even a ... Olive tree. Its fertility is marvellous, for the prodigious crops which it raises are produced, and probably have been produced almost

Amaranus, and on the east of the Jordan the hills of Moab and Gilead. On the west of the Jordan the hills are all limestone and chalk, but on the east side this is much mixed with basalt. The average rainfall of Beirut is 36

At Beirut and Damascus, the temperature is considerably higher than at Jerusalem, with as great a difference between summer and winter. The highest peak in the Holy Land, Mount Hermon, does not reach the limit of perpetual snow, which is about 10,000 feet in Central Europe.

The plants of this zone, like those of the one below it, closely resemble those of the Mediterranean basin, and especially of the hills of Greece and Italy. The prevalent orders are Compositae, Leguminosae, Gramineae, Labiateae, Umbelliferae, Cruciferae, and Boraginaceae. This zone and the one below it show the Mediterranean characteristics of often having a large number of species to a genus, which is a rare thing in Britain, of *Astragalus*. Taking Syria and Palestine as a whole, there are 132 species; of *Centauria* 47, of *Allium* 42, of *Euphorbia* 41, and of *Salix* 39—nearly 500 species to five genera. The common trees of the hill slopes are Gall Oak, *Valonia* Oak, *Pinus halepensis*, *P. Pineae*, Olive, *Terebinth*, *Plane*, *Bay Laurel*, *Styrax*, *Cedrus*, and *Crataegus Aronia*; there are no Beech, Ash, Birch, English Oak, Chestnut, Elm, Holly, and Yew. Of shrubs the most notable are the *Carob* (*Cerastonia*), *Arbutus Unedo*, and *Andrachne*, the *Judas tree*, which, with its red flowers, is very handsome in spring; *Rhus Coriaria*, *Clematis crrhosa*, *C. flammula*, *Paliurus aculeatus*, *Myrtle*, *Ray*, *Calceolome*, and other shrubby *Genistas*, *Laurel*, *Pistacia*, and *Cistus*. The *Vine*, *Fig*, *Pomegranate*, *Orange*, *Mulberry* and *Walnut* flourish. Fences are often made of *Prickly Pear* (*Opuntia*), and its fruit is eaten, but, like *Agave americana*, the *Opuntia* has been introduced from America, so that artists should be warned against introducing it into Biblical pictures. Amongst the beautiful spring flowers of this zone are *Anemone coriaria*, red and blue *Cyclamen persicum*, *Hyacinthus orientalis*, *Ranunculus asiaticus*, *Tulipa Oculus solis*, *Puschkinia*, *Lily-of-the-valley*, *Muscari comosum*, *Crocus hysmalis*, and *Gaillardetia*. There are considerable numbers of species peculiar to the Holy Land, belonging principally to the larger Mediterranean genera.

FIG. 93 THE GARDEN OF GETHSEMANE AS AT PRESENT LAY-OUT AND ENCLOSED

year by year for the last forty centuries, without any of the appliances which we in England find necessary for success." Wheat is the principal grain; sometimes the variety with compound spikes so well known in Egypt. There are also Maize, Barley, Rice, Tobacco, Hemp, and Sesamum. May is the harvest month, and after that through the dry season up to October the country looks brown and desolate, as there are no meadows or pastures. About the towns and villages there are groves of Olive, Sycamore, *Plane*, *Date*, *Palm*, *Walnut*, and *Grapes of Eschol*. The wild plants of the region are very much like those of the plains of Greece and Italy. Amongst the common woods are blue *Nigellas*, scarlet *Adonis*, crimson *Poppies*, many *Delphiniums*, species of *Euphorbiaceae*, *Borraginaceae*, and *Cruciferae*, red and blue *Pimpernels*, purple *Specularias*, great yellow *Margarites* (*Chrysanthemum coronarium*), and such grasses as *Darnel digitaria*, *Setaria*, and *Panicum Crus-galli*. The *Mandrake* (*Mandragora*), to which many kinds of mystical properties have been credited, is as common now as when *Reuben* gathered a basketful of its red berries like *Potato Apples* and gave them to his mother. There are a great many interesting plants on the sandhills. A large proportion of *Bornmüller's* collection was made on the sandhills about *Jaffa* in March and April, but taken as a whole the plants of this region are much fewer and less interesting than that of the next.

5.—ZONE OF THE HILLS UP TO 4,000 FEET

This is the most extensive and botanically the richest of the four zones. At *Hebron* the hills reach a height of 3,990 feet above sea level. At *Jerusalem* the *Mount of Olives* is 2,663 feet above the *Mediterranean* and 4,000 feet above the *Dead Sea*. The *Samaria* and *Gililee* the watershed ridge between them reaches 2,375 feet east of *Samaria*. It is but in *Mount Tabor*, 1,600 feet in the *Galilee* (Galilee) spur. Northward this region includes the *Lebanon*, *Nassairy* chain, which borders the *valley of the Orontes* on the west, and the slopes of *Lebanon*, *Anti-Lebanon*, *Cassius*, and

includes; that of the *Lebanon* is estimated by *Dr. Post* at 59 inches, of the *Anti-Lebanon* at not more than half of this last figure, and of the hills on the east of the *Jordan* at 19 or 12 inches. The mean temperature of *London* is 48° F., sink

FIG. 94 PALESTINE: ROAD FROM JERUSALEM TO BETHLEHEM.

ing to 37° in *January* and rising to 62° in *July*, with a difference between the two of 25°. The mean temperature of *Jerusalem* is 62°, sinking to 48° in *January* and rising to 77° in *July*, with a difference between the two extremes of 29°.

4.—THE REGION OF THE MOUNTAINS OVER 4,000 FEET.

This includes a long ridge on *Lebanon* and *Anti-Lebanon*, another equally long ridge of

Mount Amanosa, north of Antioch, the southern end of Mount Cassius and the two highest peaks of the Jebel-el Doring range, which forms a semicircle round the head waters of the Jordan. The highest peak of Lebanon rather exceeds 10,000 feet. Mount Hermon, at the S.E. of Anti-Lebanon, which forms a conspicuous object from Galilee and the plains of Damascus, reaches 6,400 feet. There is nothing over 4,000 feet in Palestine proper—i.e., Judaea, Samaria, and Galilee. The great peculiarity of this mountain region of the Syria flora is that, as in mountains of tropical Africa, the ordinary Arctic-alpine types so abundantly represented in Britain, the Alps, the Pyrenees, and Carpathians, do not enter it, although many of them reach the Caucasus, the mountains of Armenia, the mountains of Central Asia, and the Himalayas. The plants of the mountains of Syria are either the common plants of Britain and Central Europe or endemic species of Central European and Mediterranean genera. Sir J. D. Hooker describes as follows the ascent of the Lebanon range:—The Oak forms the prevalent arboreous vegetation below 5,000 feet. *Quercus pseudo-Coccifera* and *infectoria* (a variety of *lunata*) are not seen much above 3,000 feet, nor the Valonia Oak at so great an elevation, but above these heights some magnificent species occur. At the same elevation Junipers become common, but the most remarkable plant of the upper regions is certainly the Cedar. At the elevation of 4,000 feet on the Lebanon many plants of the Middle and Northern latitudes commence. Amongst the most conspicuous are Hawthorn, dwarf Elder, Dog Rose, Ivy, Butcher's Broom, a variety of the Barberry, Hornsuckle, Maple, and Jasmine. A little higher, 5,000-7,000 feet, occur *Cotoneaster Nummularia*, *Rhododendron ponticum*, Primrose, *Daphne obsides*, several Roses, *Potentilla*, *Juniperus communis*, *J. foetidissima*, and Cedar. Still higher up, 7,000-10,000 feet, there is no shrubby vegetation. At the elevation of 3,000-9,000 feet the beautiful silvery *Oxyria canescens* forms large tufts of pale blue where scarcely anything will grow. The most boreal forms are confined to the clefts of rocks or patches of snow. *Pteris aquilina*, which we look on in Britain as marking the upper limit of cultivation, ascends Lebanon to 6,000 feet.

PLAIN OF ES-BALLOS.

The Plain of Esraheon extends from the coast to Jordan valley, forming a triangle with its apex to the west. It takes its name from the old royal city of Jezreel, where Ahab built a splendid palace and formed a large park. The three sides of the triangle are from 12 to 18 miles long. This was the scene of the victory of Gideon and the overthrow of Saul and Jonathan. Mount Gilboa overlooks it. It is very fertile, but now, through Turkish misrule is totally desolate and uncultivated. It was at Jezreel where Naboth had his vineyard.

Above 9,000 feet are *Draba arenaria*, a small *Potentilla*, *Raabis alpina*, and others, and *Oxyria reniformis*, the only decidedly Arctic plant in the whole country. There is no Calluna, no Gorse, no Erica, no Sphagnum, no Foxglove, no Birch, no Anemone, no Wood Hyacinth, no Bilberry, no Nardus, no *Juncus squarrosus*, no Luzula, so that it is very different from a mountain in England or Scotland. Of common English plants to be seen here, but not lower down, I may mention Beech, Hazel, Yew, Primrose, Wild Strawberry, *Festuca ovina*, *Carex remota* and *C. sylvatica*, *Nephradium*, *Filix mas*, *Osmunda*, and *Aspidium angulare*. As instances of endemic or rare Oriental species I may mention *Ribes orientale*, *Ranunculus*, *Fritillaria hermontica*, *Crocus hermonensis* and *C. zonatus*, *Vilca libanotica*, *Vilca libanotica*, *Rosa Thuretii*, *Polygonum libani*, *Potentilla Kotschyana* and *P. libanotica*. J. G. Baker, F.R.S., F.L.S.

(To be concluded.)

ORCHID NOTES AND CLEANINGS.

CYPRIPEDIUM HYBRIDS.

Flowers of the following four fine hybrids are sent by Mr. R. Windsor Rickards, Usk Priory, Monmouthshire:—

CYPRIPEDIUM FRENCHAY, first shown in December 1914, and recorded in error as between *C. bellatulum* and *C. Lawrebel*, is really the result of a cross between *C. Antigonae* and *C. Lawrebel*. The broad dorsal sepal has a whitish ground tinged with rose and bearing many branched purple lines from the base to the apex. The broad petals are coloured like the dorsal sepal, with the addition of a green shade on the inner halves and dense chocolate purple spotting over the whole surface. The lip is greenish-white, with a purplish base.

CYPRIPEDIUM RAYONATUM, obtained by Mr. R. W. Rickards from the Walton Orange collection, has a fine white dorsal sepal with emerald green base and ascending spotted lines of deep purple colour. The petals are very broad, purplish-chocolate on the upper halves, and greenish yellow on the lower halves, with dark spotting at the base.

Mr. Smith also sends a two-flowered inflorescence of the rose pink *Brassia Cattleya Maroniana* (B. C. Madame Chas. Maron × C. Insi), in which the latter parent gives the form of the lip, and *Laelia Cattleya Gouhaerea* (L. C. Gottaiana × C. Dovianna) aerial, of good size, and a remarkable colour. Both the *Brassia Cattleya* and the *Laelia Cattleya* have previously been recorded from Blenheim.

ON INCREASED FOOD PRODUCTION.

CONTINUOUS CROPPING OF VEGETABLES ON THE SAME SITE.

On p. 216, J. E. refers to Onions which have occupied the same border for 25 years. Another instance of continuous cropping was mentioned by Mr. Brotherton in the issue for June 2 last, when he stated that Brussels Sprouts had occupied the same ground for 20 years in succession. In this neighbourhood Celery has been grown for 20 years on the same plot. Mr. Beckett has stated that he has grown Onions and Potatoes on the same piece of land for many continuous years. Doubtless other trustworthy instances of

FIG. 95. PALESTINE: NAZARETH FROM THE NORTH EAST, SHOWING THE SURROUNDING COUNTRY AROUND.

CYPRIPEDIUM, var. BEAR KNIGHT, between Hea Enryades and Mrs. Wm. Mestyn, has the white dorsal sepal heavily blotched with chocolate purple, the larger basal blotches being almost black. The petals and lip are similar to *C. rayonatum*, but narrower and much darker in colour.

CYPRIPEDIUM, var. BEAR KNIGHT, between Hea Enryades and Mrs. Wm. Mestyn, has the white dorsal sepal heavily blotched with chocolate purple, the larger basal blotches being almost black. The petals and lip are similar to *C. rayonatum*, but narrower and much darker in colour.

ORCHIDS FROM BLENHEIM.

MR. JAS. SMITH, Orchid grower to the Duke of Marlborough, Blenheim, Woodstock, sends a flower of *Cypridium Mauvrii*, a cross between *C. Maudiae* (*Callousm Sanderae* × *Lawrenceanum* × *Villosum*) and *C. viridissimum* (*laureum* × *Villosum*). The bloom measures 7½ inches across. It is whitish green with a white margin to the dorsal sepal, some indistinct purple lines also appearing on it and the petals, and there is a tinge of brown on the lip.

continuous cropping could be cited, but enough have been given to make one question whether rotation is necessary. The following queries are in my mind as I ponder the above citations: (1) If a few vegetables can be so grown, why not all? (2) If vegetables, why not farm crops? (3) What becomes of the supposed necessity and virtue of cropping in rotation? In accepted standard works on agriculture and horticulture we have been (and still are) taught (1) that insect and fungus pests are more liable to attack crops grown continuously on the same ground; (2) that such crops lose vigour and are consequently less able to withstand attacks; (3) that a variation of cropping minimises, if it does not altogether withhold, the food of particular insects; (4) that alteration in cropping is most economical from a manurial standpoint, because some crops require more of one kind and others more of another kind of food; (5) that shallow-rooting crops should be followed by deep-rooting crops; and (6) that the rotatory system ensures a better tillage and cleaning of the ground—each crop getting that particular cultivation best suited to its needs.

Now, what are we to say to this teaching of rotation on view of the above unquestionably successful examples of cropping by repetition of the same crop? It is not merely a book question, but farmers have taught their young men and farmers their students that cropping by rotation is the better way. Either such teaching is necessary and sound or it is not. If a crop will grow satisfactorily on a given site year after year, it need be moved? C. Turner, *Amphill Park Gardens, Bedfordshire.*

POTATO TRIAL AT BARROW-IN-FURNESS.

A TRIAL of twenty-four varieties of Potatoes conducted by Mr. W. H. Christian, Parks Superintendent at the Public Park, Barrow, gave the following results:—

Twelve well-sprouted whole sets of each variety were planted on April 25, 1917, 15 inches apart, in drills 6 inches deep and 2 feet 6 inches apart; the sides and bottom of the drills were well sprinkled with wood ash before planting, and when the plants were 4 inches high sulphate of ammonia was applied at the rate of 3 ounces per square yard. Early varieties:—Eclipse, 40g lbs.; Sharpe's Express, 35g lbs.; Improved Ring-leader, 22 lbs.; May Queen, 22 lbs.; Webb's Improved Ashlet, 16g lbs.; Middleton Early, 15 lbs.; Harbinger, 14g lbs.; Pioneer, 12g lbs. Mid-season and late varieties:—Great Scot, 62 lbs.; Scotch Russet, 56 lbs.; Heather Bonnet, 52g lbs.; Lord Amavster, 52g lbs.; British Queen, 50g lbs.; King Edward VII., 48 lbs.; Leach, 46 lbs.; Goldsaber, 44 lbs.; Golden Wonder, 42g lbs.; Come to Stay, 42 lbs.; Victory, 40g lbs.; What's Wanted, 32g lbs.; Arcan Châtel, 31 lbs.; Up-to-date, 30 lbs.; Factor, 28g lbs.; Snowdrop, 28 lbs.

A trial of artificial manures was also made. Great Scot Potatoes being used. In each case the cost of the manure was 6d., and the manure was used for 24 sets of Potatoes applied before planting, which took place on April 25, the details of planting being the same as already named. The crop was lifted on September 6, the results being as follows, viz:—

No.	Weight of set of Manure	Manure.	Weight of Potatoes lifted.
1	11a	Equal parts, Superphosphate of Lime and 80 parts of Ammonia	7 7
2	7	Barrow Corporation No. 1 Artificial Manure	7 5
3	2g	Sulphate of Ammonia	6 12
4	4g	Equal parts, Superphosphate of Lime, Sulphate of Ammonia, and Wood Ashes	6 12
5	7	Barrow Corporation No. 2 Artificial Manure	6 8
6	9	Wood Ashes	5 12
7	4g	Superphosphate of Lime	5 8
8	—	No manure	4 9

PHASEOLI'S OR DUTCH BROWN BEAN.

THROUGH the kindness of Mrs. E. Labouchere, of Billing Hill, Northampton, who was good enough to send us a little more than ½ lb. of seed last spring, we were afforded the opportunity of growing and testing the quality of the dwarf Dutch Brown Bean. The seeds were sown during the second week in May, on a south border, and the plants harvested immediately the crop was ripe; they were hung up, head downwards, in a dry, airy shed. We have now shelled them, and find the yield to be 24 lbs. I have had the opportunity of testing their culinary value cooked much in the same way as Haricot or Butter Beans, and with a little butter, pepper and salt they are very delicious and appetising. I hope to grow this Bean on a much extended scale during the coming year. When better known it should do much to stimulate the important industry of harvesting dried Beans in this country. The cropping qualities of the plant are excellent, and there was very little worthless seed in the yield. *Edwin Beckett*

THE KITCHEN GARDEN.

By J. DUNN, Foreman, Royal Gardens, Windsor.

SEED POTATOES.—Tubers intended for planting, either in pits or early borders, should be selected and placed eyes upwards in shallow boxes with a little delay as possible. Some early varieties are already making growth, and if not placed in a favourable position at once, weak, spindly shoots will be the result. It is advisable to procure as many seed Potatoes from another district as possible, and to place them where they will receive the full benefit of light and air without exposure to frost or cold draughts. Tubers intended for planting in heated pits should be placed in gentle heat at once, so that short, stocky shoots may be produced before planting takes place. Seed Potatoes intended for later plantations should be laid out thinly before growth commences.

RHUBARB.—A supply of fresh roots of Rhubarb should be placed in gentle heat every fortnight. If only a small quantity is required Rhubarb may be forced under a greenhouse stage or in a Mushroom house, provided the roots are covered with fine soil and not allowed to become dry. At first, more we force Rhubarb on beds of leaves in a slightly heated pit. The mild heat produced by the leaves is very suitable, and the same bed of roots, providing the bed is shaken up and a little fresh material is mixed with it when a fresh lot of roots is introduced. The present is a good time to trench and manure ground for new plantations of Rhubarb. If time will permit the ground should be trenched to the depth of 2 feet and a good dressing of farmyard manure applied, leaving the surface as rough as possible until March, when the plantation should be made.

WINTER SPINACH AND OTHER GREEN CROPS.

Spinach will benefit by the frequent use of the hoe during favourable weather. Remove all decaying leaves or plants, and keep the ground free from weeds. The same remark applies to young Cabbages, which should be hoed and all blanks made up. Cabbage plants which still remain in the seed-bed should be transplanted into light, sandy soil with a view to spring plantations; allow 4 inches between the plants each way.

PARSLEY.—A few box frames or spare lights should be placed over a part of the Parsley bed in order to make quite certain of a supply in case of snow. Remove all decaying leaves and other rubbish from between the rows, and stir the soil lightly with a hoe. Parsley in pits must be freely ventilated and the soil kept free from weeds.

MUSHROOMS.—Continue to collect and prepare manure for making up new Mushroom beds. Turn the material every second day, and never allow it to become sour through placing large quantities together. Beds from which spores are being gathered should be kept as near 55° as possible. Maintain a moist atmosphere by frequently damping the walls and floor of the house with a syringe. If this work is carefully carried out very little will be necessary to the bed in the way of watering, as watering is frequently detrimental to young Mushrooms. A covering of clean straw over the surface of the bed does much to keep the surface from becoming dry.

ROOTS.—A quantity of Parsnips, Jerusalem Artichokes, and other roots should be lifted and placed in store for immediate use, and sufficient protective material secured for covering the beds in case of sharp frost.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Galtton Park, Reigate.

PHALAENOPSIS.—The species of Phalaenopsis are among the most difficult to manage during the winter months. The succulent nature of their leaves, and the absence of pseudo-bulbs, make them especially susceptible to injury, and ex-

trême care and watchfulness on the part of the cultivator are necessary. *P. amabilis*, *P. Stuartiana*, *P. Sandersoniana*, and the hybrid *P. leucorhoda*, are now developing their flower-spikes. Watering should be done with the greatest care during the winter months, as an excess of moisture at the roots may cause decay in the leaves. The plants should be examined each morning, and if the Spaghnum-moss is dry it should be lightly sprinkled, as soon as the temperature of the house rises above 65°. At the same time damp the sides of the receptacles, and the roots that are clinging to them, with tepid rain-water. Care must be taken that water does not lodge in the centres of the plants or in the axils of the leaves. The spikes should not be allowed to remain on the plants long after the flowers are developed, or the plants will be weakened and permanently injured. The plants should be placed in a light position, but not exposed to direct sunshine. Green-leaved varieties, such as *P. violacea*, *P. speciosa*, *P. Sumatrana*, *P. Marie*, and *P. Luddemanniana* are still growing actively, and should be afforded sufficient water to keep the Spaghnum-moss fresh and green. The surroundings of the plants should be damped morning and afternoon, regulating the amount of moisture according to the weather. The temperature of the house during mild nights should be about 65°, with 5° increase during the daytime. Admit fresh air on all favourable occasions, but cold draughts must be prevented.

CALANTHE.—Deciduous *Calanthes* of the *vestita* section, and their hybrids, are opening their flowers. When about two-thirds of the number on the spikes are expanded the plants should be removed from their warm growing quarters to the Cattleya house. Placed among the other occupants of the house they will make a cheerful display for some weeks. After the inflorescences are cut, the plants should be allowed a complete rest on a dry shelf near the roof-glass, well exposed to the light. The temperature should not fall below 55°. Withhold water from the roots until the plants start into growth again in the spring.

PHAIUS.—From now onwards until the early spring the species and hybrids of *Phaius* will require very little water at the roots, provided their surroundings are kept moist. *P. Cooksonii*, *P. Norman*, *P. Marthaia*, and *P. amabilis* are freely-flowering hybrids, and require less room than plants of the *P. grandifolius* and *P. assamicus* varieties. *Phaio-Calante* *Sanderiana*, *P.-C. Berriana*, *P.-C. Colmanae*, and *P.-C. Arnoldiae* should be accorded similar treatment to the above. The plants are subject to attacks of thrip and scale insects, which should be kept in check by sponging the leaves frequently with an insecticide. They should be grown in an intermediate temperature, and afforded plenty of fresh air at all times.

THE HARDY FRUIT GARDEN.

By W. A. COOK, Gardener to the Hon. ARTHUR J. DAVEY, Abbots Wood, Godalming, Surrey.

WALNUTS.—On many estates most of the Walnut trees are old, and a few trees should be planted to succeed them. Walnut trees grow very rapidly, and make valuable timber if planted and staked. When planted on park or meadow land the branches should be kept about 7 feet from the ground, to allow cattle to walk or graze under them. One variety known as *Mayette-Charbette* produces very large nuts of fine flavour. *Ingram Fertilis* is of dwarfer habit of growth; the shells are thinner, and the Nuts ripen 10 days earlier. These trees are satisfactory as isolated specimens or planted in groups of five or seven at not less than 12 to 15 yards apart. When planted in groups they are better able to withstand wind storms, as single specimens are liable to be injured by gales.

FILSBERTS AND COBR can now be pruned; standard trees should have some of the inner branches pruned out. Close and short-jointed wood produces the best results. Keep the heads of bush trees shapely. Fork over the surface of the soil and keep it free from weeds and suckers. Do not allow Moss and Lichen or Ivy to grow on or near the stems. By way of top

dressing, spread some old potting-shed refuse over the roots. When making new plantations Cobnuts should form the larger portion, as they are more valuable from an economic point of view.

THE STRAWBERRY BED.—On light, sandy soils it is necessary to go over the plantation after frost to see if the young plants have been loosened. Well tread the soil down around them, and see that there are no weeds. A good top-dressing of garden refuse from the fire heap can be applied this season with much benefit to the plants. The present is a good time to prepare a plot of land for a new bed next year. This should be well trenched and left rough for exposure to the weather. It may be forked back for spring planting, or, if not required in the spring, the ground need not be idle until next season, as a crop of early Peas or Potatoes can be got off it before July.

THE FRUIT ROOM.—Apples are keeping well this season, and King of the Pippins, Cox's Orange Pippin, and Blenheim Pippin are in prime condition. Keep a little air circulating to dispel damp and prevent a musty smell. Pears *Gloii Mouceau*, Winter Nelis and Nouvelle Fulvie for dessert, and Catillac for stewing, are now in season. Cobnuts will never be in better condition for use than now, but they can be kept yet for a considerable time. They should be stored in their husks in large pots or earthenware vessels in a dry room.

GENERAL WORK.—Continue the pruning of all kinds of trees, excepting Peaches, Nectarines and Apricots, as the weather permits. Tying, nailing, top-dressing, root pruning and spraying should also be pushed forward. This last operation should be done very thoroughly, and if possible a second time, as I have found several living specimens of the Lucky Moth after a first spraying. Where there are evidences of a plentiful supply of bloom, cut the shoots well back, with due regard to a proper distribution of the branches, especially of young trees. If a branch is required to fill a vacant space, prune one of the shoots either above or below the vacant spot (whichever is the stronger) to the base, and then train in two shoots from the break next season. In the case of a fan-shaped tree, rearrange the whole of the branches. Be on the alert for sparrows taking the bark from 4-woodbushes and Currants in cold weather, and take preventive measures. Lime or soot mixed with petroleum, sprayed over the trees, is a good preventive, or other may be applied in a dry form, but this is quite to be done often, as heavy rains will wash off the material. Small ornamental trees may be protected with black cotton or thread with good results.

FRUITS UNDER GLASS.

By Jas. HENSON, Head Gardener at Ginn's-bury House, Acton, W.

OLD CHERRY TREES UNDER GLASS. These trees should be pruned forthwith, and if the growth has been too luxuriant the roots should also be pruned a little. Then let the house be thoroughly cleaned and the trees be lightly dressed with a safe insecticide against dormant insect pests. After that work is completed fork the border lightly and apply a top-dressing of rich loam mixed with fine mortar rubble. When the whole of the work is completed throw the house wide open.

YOUNG POT VINES.—Examine the soil of pot vines to see if moisture is needed, for it must not be allowed to become excessively dry. I prefer to grow the plants out-of-doors, with the pots plunged to safeguard them from damage by frost. Cut the roots back to within 2 feet of the pot. Meanwhile prepare soil for potting them into their fruiting pots soon after the turn of the year. The soil should be in a fairly dry condition, and consist chiefly of good turfy loam with a little finely sifted forward manure and sifted mortar rubble. Select the fresh pots and wash them in good time. Do the final pruning rather in advance of the potting, cutting back to a prominent eye at the base. After the vines are potted they should still be kept cool for a few weeks. They may be started in

a Melon pit, but bottom heat should not be employed for some time to come—in fact, it may be dispensed with altogether.

LATE GRAPES.—Pay constant attention now to bunches still hanging on the vines. Three times a week they should be examined for diseased berries and signs of drip. Wind a little wadding round the point of a small stick, and when a berry is taken out, wipe the adjoining berries. Remove all leaves as they fall, and keep the house as dry as possible, with just sufficient warmth in the pipes to dispel any damp. Make it a practice to use these bunches first that show any signs of shrivelling. In order also to extend the supply reduce the quantity cut each day to the lowest acceptable minimum. Get the bottles in readiness for bottling the crop soon after Christmas Day. Clean the bottles well, and place some small pieces of paper in each bottle, filling them with rain-water. As soon as these late Grapes are cut the vines should be pruned. Apply styptic to each cut; it may not at present be needed, but it will help to check bleeding when the sap rises again. Thoroughly soak the border and clean the vines, prick over the surface, and add a top-dressing of good, loamy soil. Then throw the house open to the wind and weather if possible. Late Grapes have kept better than usual this autumn, especially late Muscats and Gros Colmar.

FIGS IN POTS.—The young roots of Figs are susceptible to injury by frost. Keep them in a temperature above freezing point if possible, or, failing this, bed them in cool ashes. Do not use litter, or the shelter thus given will be taken advantage of by rats and mice. The latter do a great deal of damage to the stems by gnawing them. If any Figs have been attacked by scale insects, dress them with an insecticide. A good method is to lay the pots on their sides, and so prevent the liquid from running down the stem. Cleanse the walls, the paint and the trellis work, removing at the same time the surface soil of the borders, and lightly top-dress them with turfy loam and charcoal sifted mortar rubble.

PLANTS UNDER GLASS.

By F. G. WYSTON, Gardener to Lady Northwick, Eastwell Park, Kent.

PRIMULA SINENSIS. Plants now commencing to show up their flower spikes should be encouraged by a pinch of artificial plant food, and a little weak manure water or soot water applied about once a week. Keep the temperature of the house from 50° to 55°; the lower figure will suit quite well for the night temperature. Give a little air when the temperature rises above 55°, and let the heat run up to 60° by sunshine before increasing it further.

PRIMULA OBCONICA. This thrives best in a damp atmosphere, such as a cool frame or cold bed, but as the flower spikes develop the plants should be removed to the conservatory or flowering house. When established in the flowering pots, and well rooted, a good supply of water is required. Dryness at the root in a dry atmosphere, or a high temperature, will soon cause shabby foliage and stunted flower spikes. Gentle stimulants should be afforded as recommended for *P. sinensis*, and this will tend to keep the plants flowering over a long period.

P. MALACOIDES AND P. KEWENSIS.—Both these species, and the one above, are excellent plants for the amateur grower, as they all succeed in similar conditions. *P. kewensis* has clear yellow blooms, and makes a change from the range of colour found in the other varieties. It throws up a good spike, and if well treated will remain in good condition for several months. All *Primulas* which thrive in cool treatment are very much at home planted under the stages of the greenhouse, fairly close to the path.

GENERAL REMARKS.—In bad weather, when work out-of-doors is at a standstill, thoroughly clean and rearrange the plant houses. Wash the wood and ironwork, and limewash back walls and the brickwork over the stages. A little paraffin oil in the limewash is of great value in making the wash more adhesive, and it also increases the cleansing value, by penetrating

holes and crevices, which are often the winter haunts of insect pests. If small gravel or spar is used on the stages this should be washed, or replaced with fresh material. If the house contains climbers trained to the roof or pillars the plants should be examined, all superfluous growth cut out, and the remaining shoots cleaned. After the house is thoroughly cleaned the plants should be carefully rearranged. Above all things, do not crowd the plants at this season. It is better to devote time and space to growing six plants well than to have double or treble the number of poor specimens. Foliage plants will be much benefited by sponging their leaves; such plants as *Palms*, *Cedraums* (*Crotons*), and *Dracenas* should be sponged once or oftener during the next month or two. The greatest care is necessary in sponging fine-foliage plants to prevent splitting or crumpling the leaves. The smaller plants, which may be required for use as table specimens, are best kept together on a shelf near the roof-glass, where they will be fully exposed to sunlight.

THE FLOWER GARDEN.

By W. J. GRISSE, Gardener to Mrs. DEBRIERE, Kew Hall, Staffordshire.

PERENNIAL ASTERS.—There is no advantage in retaining the old clumps of *Michaelmas Daisies*, as much better results are obtained by lifting and dividing the plants every two or three years. Select small pieces from the outside of the old clumps; the centre portions are usually weak and exhausted, and should be discarded. Surplus plants can be used to furnish vacant spaces in shrubberies, or a reserve bed can be planted to furnish cut flowers for decoration. *Aster multiflorus grandiflorus* is a very rich blue colour, and dwarf in habit, and is sometimes mistaken for *Erigeron* species. It is excellent for decorative purposes, and lasts a long time in water. Grouped in the foreground of herbaceous or mixed borders the plants are very effective.

LILYUM. In cold, wet districts it is safer to pot up directly they are received, bulbs of *Lilium auratum*, *L. longiflorum*, and *L. speciosum*. Place them in a cool house or frame, and keep them rather dry until growth commences. By March they should be ready for planting in their flower or quarters outside. Many Liliums are handy, and may be planted now. A deep, moist loam, in which will decayed manure, peat, and leaf-mould have been incorporated, will suit them. Suitable positions and aspects must be selected for the various species and varieties. Care in planting is an important detail, especially with the stem-rooting varieties. Liliums are moisture-loving plants, but they will not tolerate stagnant moisture or sour soil.

PROTECTING SPRING BEDDING PLANTS.—It will be advisable at this period to afford some slight protection to spring bedding plants, especially Wallflowers. In many gardens last winter nearly all the Wallflowers were killed by frosts and winds. Suitable protection may be obtained by netting, branches of Yew or other evergreens about 2 inches in length round the inside of the covers. When dealing with large beds it will be necessary to place a few branches among the plants about 2 feet apart.

HARDY HEATHS. Soil containing lime does not suit *Phloxodendrons* or Hardy Heaths. The ground for these plants should be prepared some time in advance, and dug to a depth of at least 12 inches. Incorporate a liberal quantity of well-decayed manure and leaf-mould. Peat may be used with advantage, but it is not necessary where the soil is loamy and free from lime. Leave the surface as rough as possible for several weeks before planting; the levelling process can then be done with a wooden rake. On no account should the ground be forked over, as firm planting is essential. Heaths are excellent plants for covering banks, but the best effect is obtained by planting bold, irregular groups along woodland walks. A selection of varieties may be made that will give flowers through the greater part of the year. *Erica curma* and the white variety, *E. hebecea*, also should be included in any selection.

EDITORIAL NOTICE.

Editors and Publisher.—Our correspondents would oblige us by sending answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHERS; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 36.5.

ACTUAL TEMPERATURE.—Gardens' Office, 41, Wellington Street, Covent Garden, London. Thursday, December 20, 1917. Bar 29.7, temp 35.5. Weather Thick fog.

At the present time, when so much interest in the Potato is centred upon the Food Value of the Potato, it may be recalled that it took many years after its introduction to Europe in the sixteenth century for the tuber to be recognised as one of the chief foods. In the early days the doctors joined with the public in looking askance at the newcomer. It was accused of being a generator of leprosy, and Lemery, in his *Traité des Drogues Simples*, referred to the Potato so contemptuously that the "noble tuber" remained up to the end of the 18th century under a cloud of suspicion.

It was urged against the Potato that it provokes flatulence, that it could never be cleaned of its "impurities," that it caused those who fed on it to grow stout and lazy. On the contrary, Parmentier and Vauclavaux vaunted the value of the Potato in scarcely less extravagant terms, ascribed to it medicinal virtues, and averred that it possessed the power of conferring fertility on peoples, citing as "evidence" the rapid increase in population in Germany and the large proportion of twins in Ireland.

The Press of the period joined in the denunciation of the Potato, and the French Government was overwhelmed with petitions calling for the suppression of all cultivation of the Potato.

In order to settle the matter, in 1792, the Contrôleur Général de Finance, addressed a letter to the Faculty of Medicine

on February 26, 1771, inviting its members to inquire into the allegations. Thus the Potato was put upon its trial.

It was decided to submit it to trial by ordeal—of chemical analysis. As a result it was discovered that Potatoes contain a white powder similar to the starch of cereals, woody fibre, a mucilaginous juice with no special properties, and a large quantity, 75 per cent., of water. From that time the Faculty took the Potato under its wing. Tissot, the celebrated French doctor, writing to the Swiss agriculturist, Herzel, assured him of the value of the Potato and its edibility—you can eat it as often as you can eat bread—and the same authority maintained that it is the best of all diets for nervous women.

At about the same time another savant—and it is interesting to observe that savants can exaggerate like unlearned folk—expatiated on its anti-scorbutic properties. Those properties the Potato indeed possesses, and having regard to the fact that Potatoes make up a large proportion of the fresh food of large sections of the community during winter, they are undoubtedly important. Yet, according to the most recent researches, the Potato is inferior to many other vegetables—Onions, Cabbage, and others—in anti-scorbutic property.

The hymn of Potato praise chanted by the learned continues. Saint Hilaire proclaims it a specific against insomnia, and states that he had tried it with good effect on his servants; though some may incline to the observation that the malady of insomnia is not now prevalent among domestic servants! Parmentier expresses himself as doubtful. He thinks that the sedative effects would be likely to wear off as the domestic became accustomed to Potatoes; but admits that a Potato diet is "calming."

The Italian doctor, Filippo Baldini, studies the influence of the Potato on the circulation, and claims that it is a good corrective of "acidity." Later on the potato salts contained in the Potato were regarded as the purifying elements.

The most recent attack on the Potato is perhaps the gravest. It is claimed in the *Brevière de la Branté*—composed by a lady, that all who wish to remain young and pretty must eschew the use of the Potato; but the doctor's championship has prevailed—combined with the poor quality of war-bread—to induce even the youngest and prettiest among us to go on eating Potatoes and risk the consequences.

The last word on the subject was said long ago by the poet, Heinrich Heine: "Pourquoi chanter la rose? Que le poète chante la pomme de terre qui nourrit le peuple."

NEW PLANTS FROM BRITISH HONDURAS.—Mr. S. F. BLAKE describes, in *Contributions from the Gray Herbarium of Harvard University*, new series No. LII, a number of novelties from this still little known British Possession. *Mylonearpa paniculata*, an arboreal member of the Urticaceae; *Millopauglia biophylla*, a third species of a genus of Polygonaceae peculiar to

the region; a number of Lauraceae, Mimosaceae, and various other families make up a total of nearly 50 additions. *Belandra* is a new genus of Apocynaceae, allied to *Echites* and *Odontadenia*.

A CROP OF HAY IN MID-ATLANTIC.—The vegetation of remote islands offers many anomalies and many surprises. Ascension is an ocean peak with a forty-square-mile base and no climate worth mentioning, and little visible vegetation in its lower parts. Suddenly, as we learn from the *Kew Bulletin*, a grass has appeared in the great abundance in the lowland plain, and the crop this season was so heavy that many tons of hay might have been saved had the authorities been prepared for it. As it was, a small stack was made as an experiment, and horses and mules of the garrison were turned out to graze. "Whether," the Kew correspondent writes, "the grass is a perennial and really useful remains to be seen; but the animals are very fond of it." Beautiful rains, the first experienced for a generation, preceded this heavy crop of a single species of grass. Dr. STAFF has identified the grass as *Enneapogon mollis*, which has not previously been recorded from Ascension; but it is scattered over a wide area in dry districts of tropical Africa, and has also been collected in Madagascar and the Punjab. A photograph illustrates the article showing the hayfield and haymakers.

CHINESE SPECIES MAKING.—"W. B. H.," in the sympathetic obituary notice of the late DAVID OLIVER, which he has contributed to the *Proceedings of the Royal Society**, recounts several curious instances which go to show the confounding nature of some systematic botanists, and to confirm BRET HARTE'S diagnosis that

"For ways that are dark,
For tricks that are vain,

The heathen Chinese is peculiar."

As an illustration:—Among A. HENRY'S Chinese plants was a specimen with leaves like an *Eschulus*, and terminal clusters of Viburnum-like flowers. On this specimen was founded a new genus, *Actinotinus*. A little later another botanical puzzle presented itself. This time papilionaceous flowers and foliage, unlike that associated with the Leguminosae, presented themselves. The specimens were shown by OLIVER to BOTTING HEMSLEY and N. E. BROWN, the latter of whom recognised that the species was made by the art of man and not by Nature. Reference to the specimen on which *actinotinus* was founded revealed a like evidence of guile. Dr. BOTTING HEMSLEY confesses that he also was victimised in a similar manner some years later, when he described the leaves of a *Daphniphyllum* and the flowers of a *Rhododendron* as a new species of the latter genus, but in that case Justice ALBERT tardily came to the assistance of British botany, for once again the same Chinese hand tried its cunning, this time with Mr. E. H. WILSON, and lost three weeks' wages in the transaction.

BLINDED SOLDIERS' CHILDREN.—In connection with the Sir ARTHUR PEARSON'S fund in aid of the children of blinded soldiers, a special branch of the fund has been inaugurated to cover the seed and allied trades. Mr. ARBYN TREVOR-BATTYE, Ashford Chase, Petersfield, Hants, has the matter in hand, and he states that Messrs. SUTTON AND SONS have promised fifty pounds. This fact encourages the hope that other prominent horticultural firms will shortly follow suit. The cause is so well known to our readers through the columns of the daily press that we need not reproduce all the details supplied by Mr. TREVOR-BATTYE, but we feel that such a deserving fund is certain to receive due support from those to whom this special appeal is made. Letters should be sent to Mr. TREVOR-BATTYE at the address given above.

VITAMINES: NATURE'S PREVENTIVE MEDICINES.—When Captain Cook cured his men of scurvy by providing them with fresh vegetables he made a discovery the importance of which, masked by the banality of the medicine, it has taken a hundred years to estimate. It is now known that the vegetables which exorcised the scurvy did so by reason of the fact that they contain minute quantities of definite chemical substances—of unknown kind—which are Nature's indispensable and infallible preventive medicines. A dish which lacks these remarkable substances, no matter how generous it may be in respect of fats and carbohydrates and protein, no matter how liberal its allowance of calories, is nothing else than a negative poison. Not only does an animal or human being fed on such a vitaminless diet fail to thrive, but

aleurone grain layer of the Wheat or Rice or Maize grain, but rather and chiefly in the germ or embryo. Now in the modern method of milling every ingenuity has been expended in separating not only the chaff from the Wheat, but also in removing the embryo, with the result that machine-made white flour is seriously deficient in those vegetable preventive medicines—the vitamins—the presence of which in food is essential to the maintenance of health. Whole meal bread, on the contrary, contains the embryo or germ of the Wheat grains, and hence the vitamins. That these are flour facts has been amply proven by actual investigation and the authors, Miss CHICK and Miss HUME, have carried our knowledge further by demonstrating the fact that it is the vitamins contained in the germ of cereal grains

unless they are accompanied by a sufficient ration of food which contains the vitamins they lack. In the case of theberi vitamin, it is satisfactory to learn that this, one of the gentler health, is not destroyed by an exposure to boiling point (100° C.) for two hours. Hence bread or biscuit, provided they contain the germ as well as the endosperm of the Wheat grain, will retain its vitamins unimpaired.

WAR ITEMS. M. ALEXANDRE DERASIN, son of M. DERASIN VALETTE, Vice-President of the French National Horticultural Society, was killed in action on September 5.

M. MAURICE BLOU, eldest son of M. FRANÇOIS BLOU, a foreman in the employ of Messrs. VILMORIN, ANSELIN and Co., rue de Reuilly, Paris, has also been killed in action.

FIG. 36.—PALESTINE. DATE PALMS, OPUNTIAS, AND OTHER PLANTS GROWING AT LIBERTY ON THE SHORES OF THE SEA OF GALILEE (1870, p. 250).

it contracts diseases such as scurvy and beri-beri, to which it rapidly succumbs. Furthermore, the vitamin or natural preventive medicine which protects the body from beri-beri appears to be quite distinct from that which protects it from scurvy. The occurrence of such diseases as those just mentioned among our expeditionary forces has caused attention to be directed yet more closely to the vitamins, and to the rations supplied to these forces. The most recent investigations* show that the vitamin which is the natural preventive of beri-beri, is contained not so much in the bran (pericarp and

which are responsible for deterring the body from the diseases already mentioned, and that it food substances are deprived of their vitamins, disease-subjects. The authors in a subsequent paper† have investigated the effect of temperature in the beri-beri vitamin, and conclude from their researches that the vitamins are as fragile as they are fateful. If food substances are heated for even a short time to a temperature 20° above boiling point, the vitamins disappear, and the healthfulness of the food is in consequence impaired. In so far therefore as preserved foods are prepared by processes involving such high temperatures, their use as a main source of food is to be deprecated.

THE FIRST FIFTY YEARS OF THE AUCKLAND INSTITUTE AND MUSEUM.—The citizens of Auckland (New Zealand), have celebrated the jubilee of their scientific foundation by the issue of a condensed illustrated history of its development, from the sympathetic pen of Mr. T. F. UHLESMAN, secretary and curator almost from the inception of the establishment. The "New Zealand Institute" has now branches in the leading towns of the Dominion, but the Auckland branch is twice as numerous as the next highest. It was started, and has been maintained, by private and civic enterprise. At the close of its first year it had a roll of 63 members; its total revenue amounted to the same number of pounds, and there was a small balance at the end of the year. Now there is a membership of nearly 300,

* "The Distribution in Wheat, Rice, and Maize Grains of the Substance the Deficiency of which in a Diet Causes Beri-beri in Man," by Harriette Chick and E. M. Hume, *Proc. Roy. Soc. B.*, 20, No. 13, 1924.

with an income of £1,700, and invested capital of about £1,000. This sounds like a prosperous condition; but larger premises are urgently needed, and Mr. CRUISEMAN'S report is an appeal for funds. The Maori Collection is a very valuable section of the Museum, and irreplaceable; yet it is not safely housed.

SHOREA AND GORDONIA.—The Straits Branch of the Royal Asiatic Society Journal, No. 76, contains two or three articles by Mr. J. H. BENNETT, Director of the Singapore Botanic Gardens. In "Notes on Dipterocarps" the

TREES AND SHRUBS.

BERBERIS VIRESCENS.

THE profusion in which new species of *Berberis* have come into cultivation in this country, ought not to lead to the neglect of some of the older kinds. *Berberis virescens* was found by Sir Joseph Hooker in Sikkim so long ago as 1849. It is deciduous and not to be highly esteemed for its flowers, which are pale greenish yellow (whence its specific name), nor for its red fruit, which it declines to ripen with me. But it is an

it was introduced by Wilson, from China. In an old issue of the *Kew Bulletin*, entitled "A Published List of Plants introduced to Cultivation, 1876 to 1896," the species is mentioned as having been figured in the *Florist and Pomologist* in 1884, and is also included in the first *Kew Hand List of Trees and Shrubs*, 1894. In *Trees and Shrubs Hardy in the British Isles*, Mr. Bean states that it was first introduced to St. Petersburg about 1830 from Manchuria, and from China by Wilson in 1900. The Chinese form is, according to Mr. Bean, superior to the typical kind, and is known

FIG. 97.—*LONICERA MAACKII*: FLOWERS CREAMY-WHITE.

author describes and figures the seeds and their germination of some species of *Shorea*. *Gordonia* is represented by two species on the Atlantic seaboard of North America, namely, *G. Las othius* and *G. pubescens*, and about 20 species widely spread in tropical Asia. Both the American species are, or have been, in cultivation in this country; but *G. pubescens* is said to be extinct in a wild state. *G. axillaris*, a *G. las othius* group, was in cultivation at Kew in 1812, and it was figured in the *Botanical Magazine*, t. 17, p. 249. A figure of the same species appeared in the *Gardeners' Chronicle* on June 11, 1917.

exceedingly pleasing object at this season of mid winter, for the gracefully arching stems are of a bright, ruddy orange, much the same hue as the upper branches of an old Scots Pine, but smooth and shining. I know but one private garden, besides our own, where it grows; I should be sorry to be without it in the short, dark days. *Herbert Maxwell, Monmouth.*

LONICERA MAACKII

THIS shrubby Honeysuckle (see fig. 97), which is so highly spoken of by Mr. H. Kempshall on p. 242, was known in this country before

as variety *podocarpa*. Franchet. He refers to it as one of the most beautiful of bush Honeysuckles. An interesting feature connected with this *Lonicera* is that it was given an Award of Merit by the Floral Committee of the Royal Horticultural Society on June 7, 1907, and again on June 8, 1915. It is one of the few instances in which the same award has been made twice to a plant. *Hydrangea Madame Emile Mouillière* is one of that limited number. *W. T.*

PUBLICATIONS RECEIVED.—*Around the Year in the Garden*. By Frederick Frye Rockwell. (London: Macmillan & Co.) Price 10s. net.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

CROPS AND STOCK ON THE HOME FARM.—I am much interested in the articles by Mr. E. Molyneux on farm matters; they are very helpful to the many gardener backbits. What has been done this year with the land by the working-classes clearly shows what they would do if given greater opportunities. The Royal Horticultural Society has given good advice through its panel gardeners to the large class of very small cultivators. I should like to see every cottager able to keep his pig, with a garden to support the same (and his family). *L. R. Adams, Watlington Park, Oxon.*

FRUITING TREES AND SHRUBS (see pp. 226, 242).—*Lagerstroemia indica* is fully deserving of all the praise bestowed upon it by Mr. Kempshall, and the specimen at Abbotsbury must indeed be a beautiful one. There is a very good tree in these gardens, which passed through last winter quite unharmed, and though I have not had the pleasure of seeing it flower it is a real gem when in its autumn garb. Another shrub of great value in the same manner is *Andromeda arborea*. *Liquidambar styraciflua*, generally recognised for its beautiful autumn tints, excelled itself this autumn, and the specimen at Fota, which, when last measured, was 52 feet high, with a girth of 7 feet at 4 feet from the ground, made a pleasing sight. *Parrotia persica* is carrying nut-like clusters of fruit, and this season's flower-buds are just expanding. Two other shrubs carrying solitary fruits are *Osmantinus Delavayi* and *Hex Pomei*. *Drimys aromatica* carried a profusion of clusters of black fruits not unlike *Privet* berries, and *Azara microphylla* fruited freely. On the morning of the 3rd inst. we had 12" of frost, which completely spoilt our *Hydrangeas*, both blue and pink-flowered, but which had up till then retained much of their freshness of colour. Similarly *Carotus Gloride Versailles* suffered, but *Lapageria rosea* flowering on a north wall entirely unprotected is not one bit the worse for the cold. *Kenneth Bickett, Fota Gardens, Queenstown.*

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

November 15. *Committee present*. The Rev. J. Crombeldine in the chair, Messrs. R. Ashworth, D. A. Cowan, J. C. Cowan, J. C. Whyler, A. G. Ellwood, J. Evans, P. Foster, J. Howes, A. J. Keeling, J. Lupton, D. M. Good, F. K. Sander, W. Shackleton, H. Thorp, and H. Arthur (secretary).

GROUPS.

The following medals were awarded to collectors: Silver Gift Medal to R. Ashworth, Fota, Newchurch (for *Mr. Devonport*). Large Silver Medals to Col. Sir J. Bethune-Gordon, Bart, M.P., Blackburn (for *Mr. J. Lupton*); and T. Worsley, Esq., Haslington (for *Mr. T. Wood*). Silver Medals to JOHN HORTLEY, Esq., Morley (for *Mr. Cooper*); MESSRS. CYFFER AND SONS, Cheltenham; and MESSRS. SANDERS, St. Albans.

AWARDS.

FIRST CLASS CERTIFICATES.

Odontoglossum Golden Owl and *Sophro-Cathepa Dorca magnifica* (*C. aurca* × *S. C. Davis*), both from S. GENTRIX, Esq.

Odontoglossum Edna van Beauty (*Rosen* × *ardentissimum*), *Laelia Cattleya Gothroyi* (*C. Titania* × *L. C. St. Gothroyi*), both from P. SMITH, Esq.

Cyclopogon Gen. Albany (*Alca Corgels* × *Bonal George*), from T. WORSLEY, Esq.

Cattleya Falcata albo-Regina, from Messrs SANDERS.

AWARDS OF MERIT.

Cattleya amoenilliflora, *Ashworthae* (*regina* × *Mendleyi*), *C. Falcata alba* var. *Ashworthiae*, *C. var. schlandensis*, *C. lobata Briggs Bury*, *Laelia*

Cattleya Hadrian Ashworthae, *L. C. Orion Ashworthae*, and *Brassia-Laelio-Cattleya Ashworthae* (*B. L. C. Cooksoni* × *C. lobata*), all from R. ASHWORTH.

Cyclopogon Gen. Pushing (*Alca-Lanman* × *regina splendens*), and *C. Horrocksum* (*Alca-Lanman* × *S. C. Davis*), both from T. WORSLEY, Esq.

Laelia Cattleya West Point var. L. C. Capper (*C. C. Capper*), and *Cyclopogon Golden Albany* (*Alca West Point* var.), both from S. GENTRIX, Esq.

Odontoglossum crispum Septah, from Dr. CRAVEN MOORE.

Cattleya Trilobata (*C. Tronca Grand Monarch* × *C. Clifton*), from P. SMITH, Esq.

FIRST CLASS AWARD OF APPRECIATION.

Odontoglossum Dorothae (*Doris* × *crispum*) from Dr. CRAVEN MOORE.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

DECEMBER 10.—The monthly meeting of this society was held in the R.H.S. Hall on Monday, the 10th inst., Mr. Charles H. Curtis presiding. Seven new members were elected.

The sick pay for the month on the ordinary side amounted to £77 10s. 11d., and on the Station side to £26 10s., and maternity claims to £4 10s.

Obituary.

FRED C. SMALE. We regret to record the death, on the 30th inst., of Mr. F. C. Smale, son of Mr. W. B. Smale, nurseryman, of Torquay. Deceased, who was fifty-two years of age, had assisted his father to a considerable extent in the management of the nurseries. He took an especial interest in the cultivation of *Chrysothamnus*, and was in the habit of lecturing on the subject and judging at the exhibitions. Besides his work in the nursery, he was in the habit of writing for a number of magazines.

WALTER T. WARE. We learn with deep regret of the death of Mr. Walter T. Ware, at Burrow Castle, Bath. Mr. Ware had been ill for about two years, and on Friday, the 14th inst., he had a stroke, which terminated fatally two days later. Deceased, who was sixty-two years of age, was the son of Mr. F. S. Ware, who established a business at Totterdown.

Mr. Ware engaged an interest in his own account, and subsequently became one of the largest flower growers in the trade. In the development of the British bulb-growing industry Mr. Ware occupied a very prominent position, at 1, 4, and 5, Inglescombe, in Lincolnshire, and in Wiltshire, he had a large area under *Daffodils*, *Tulips*, *Lily-of-the-Valley*, and other flowers. As a grower and exporter of Tulips he had no superior and few equals. In recent years he became an enthusiastic racer of Tulips, and during 1916 and 1917 he exhibited a number of excellent seedlings, notably *Empire*, *Nivama*, *Winner*, *Lady Love*, *Inglescombe Manye*, *Zella*, and *Asturias*; these varieties secured the Award of Merit of the Royal Horticultural Society. Mr. Ware's enthusiasm for Tulips was almost equalled by his interest in new *Daffodils*, of which he purchased many for the purpose of raising stocks. Few men could so speedily appraise the value of a new Tulip or Daffodil in the market point of view. For many years Mr. Ware was a member of the R.H.S. Narcissus and Tulip Committee, and during the present year he was the holder of the Peter Barr Memorial Cup, awarded unanimously by the Committee for good work done in connection with Daffodils. He was also treasurer of the London Daffodil Show Fund until his health began to fail, and he was rarely absent from the London and Birmingham shows. He was also a member of the Committee of the British Wholesale Florists' Federation and a generous supporter of its work, and a member of the Horticultural Club. The burial took place at Locksbrook Cemetery, Bath, on Thursday last.

CROPS AND STOCK ON THE HOME FARM.

HEDGES.

Now is the time to trim, cut down, and relay hedges where they are overgrown. Many an Out crop last harvest was retarded in its ripening and drying owing to the high hedges, which prevented a free circulation of air, wind, and sunshine, especially in the case of the sheaves near the hedges. Some discrimination is, of course, necessary in cutting hedges around pasture fields where cattle are grazed, as in such fields thick hedges are of the utmost value in providing shelter for the animals during wet or cold weather.

Where a hedge has become thin at the base, and it is desired to produce a closer growth, it should be cut within 6 inches of the ground, unless it is required at once as a shelter. In such cases it should be splayed, i.e., partly cut through and laid to the height required for a foundation.

In the case of cereal or Clover fields, it is wise to cut the hedges down to within a few inches of the ground, unless it is imperative that there should be a cattle fence around the fields.

Ditches for draining the surplus water from wet land should be closely attended to and cleaned well below the pipes or open drains which connect with the main outlet. Waterlogged soil is detrimental to the Wheat plant, especially in the autumn and winter, when late-sown plants are coming through the soil.

SWEDES.

On the whole, the growth of Swedes is satisfactory in bulk. Where the seed was sown too early, however, there are already signs of premature decay of the roots, especially among plants affected by mildew during October. The period of sowing the seed varies much in different counties. In the North of England and Scotland Swedes are sown during the first half of May, while in the South of England the middle of June is early enough. Indeed, those sown at the end of the month often keep best, and if not so large in the root, are of better quality, and less liable to decay or to run to seed.

Mildew is generally caused by the plants having attained their full growth by the time a spell of drought sets in in August and September. The growth is then at a standstill, and the plants more liable to a fungous attack. In some parts "pitting" the roots in the field is a general practice, especially where they are required as early spring food for ewes and lambs on the fields. With such severe weather as that experienced last winter the "pitted" Swedes were a boon to those who took the precaution to prepare them. Many acres were spoilt by frost, and much valuable sheep food lost.

The method of "pitting" the roots is quite simple. Pull them up without interfering with the tops or roots, throw them into round, conical heaps of about four bushels each, and cover them with 6 inches of soil. The "pitting" also checks the spring growth, which lowers their quality as food for April and May. The roots should be thrown out of the pits several days before they are required by the sheep to allow the blanching shoots to wither. The shoots are not wholesome for sheep, often causing scour. *E. Molyneux.*

CATTLE AND HORSE FEEDING.

The President of the Board of Agriculture draws attention to the danger of using as food for horses or cattle any foods or mixtures containing poisonous seeds, such as Castor seed, Rangoon Bean, *Lathyrus*, etc. Seeds that have been removed from those required for crushing in oil mills are sometimes sold for use in the composition of feeding stuffs, but in order to avoid the risk of poisoning stock it is necessary that all grains of unusual appearance, especially foreign grains, should be submitted to qualified experts for identification before being used for this purpose. It should be borne in mind that a seller of a feeding stuff which contains deleterious ingredients is not only liable to prosecution under the Fertilisers and Feeding Stuffs Act, 1906, but may also be held liable for injury caused to stock by the use of such food.

FARMING OUTLOOK.

The monthly agricultural report of the Board of Agriculture states that, except in Wales and the north-west, the weather during November was favourable for autumn cultivation and the sowing of crops, especially on the eastern side of the country. Sowing in the important corn-growing counties has consequently been pushed on rapidly, and is more forward than last year, and, in the north-east more particularly, is often more advanced than usual. In the west, where the season has been much later, work is not so well advanced, but progress was made during the latter part of the month.

About 70 per cent. of the area intended for wheat has already been sown, and, as compared with December 1 last year, the area actually sown appears to be from 10 to 15 per cent. greater, this percentage being exceeded in the north-east. Generally speaking, most of the work was done in favourable conditions, and where the crop is up, it is everywhere a healthy and satisfactory plant. In some parts of the west and Wales, however, much of the land was too wet to be worked. Other autumn-sown crops also appear quite satisfactory. Of Winter Barley and Beans rather less is reported to have been sown, and of Oats and Rye about the same, as at this time last year, but, as with Wheat, slightly more has been got in the east than in the west.

Potatoes have now practically all been harvested, except in some western districts; and, with the same exceptions, the tubers are generally sound. The total production on farms is returned at 3,540,000 tons—835,000 tons, or 33 per cent., more than last year, and the largest crop raised since returns were first collected in 1885. The yield per acre, 6.57 tons, is also very good. Turnips and Swedes produced 12,164,000 tons, or 12.55 tons per acre; this is below the average, owing to a shortage mainly in the north-eastern counties. The quality of these roots is variable; Turnips being frequently rather poor, but Swedes are, in most districts, better. Mangolds are a large crop, and generally of good quality; their yield amounts to 8,492,000 tons, or 21.99 tons per acre, which is 2½ tons above average. The total production of these roots is thus greater than last year, Turnips and Swedes being 820,000 tons less, but Mangolds being 1,140,000 tons more.

ALLOTMENTS: *J. T.* Write to the Secretary, Scottish National Union of Allotment Holders, 1, Rutland Square, Edinburgh.

APPLES AND PEARS SPOTTING: *H. O.* Presumably you refer to spotting by scab. It is useless to spray in the winter unless there is scab on the wood, and even then it is doubtful. Scabby shoots should be cut off below the diseased parts, the cuttings being burnt. After the blossoms are set, spray with Bordeaux mixture or lime-sulphur of summer strength, again a fortnight later, and a third time three or four weeks later, still if scab shows on foliage or fruit. Once spraying is not sufficient. In the United States lime-sulphur has proved at least as effective as Bordeaux mixture, and it is less likely to injure the foliage of tender varieties of Apples. For Cox's Orange Pippin only a very weak solution of either specific is safe.

ASPIDIOTHA LEAVES SPOTTED: *H. H. S.* The injury has been caused by some external agency, and is not due to fungous disease. The appearance of the spots suggests damage by a corrosive fluid. Leaves are often spotted in the same manner in summer by burning, through the sun's rays falling on drops of moisture, which act as lenses, and focus the rays in the same manner as a magnifying glass.

CULTURE OF PLANTS: FRUIT TREES: *E. S. M.*

Wages vary so greatly in different parts of the country that no fixed rate can be given. But as an able-bodied man employed on the land is legally entitled to at least 25s. per week, and pruning is skilled work, 3d. per hour would not be excessive. A jobbing gardener should now get at least 6d. per hour when he works all day in the same place, and at least 3d. per hour if he goes for only half a day or less at a time. In some parts of the country these rates are exceeded.

GRUBS ON CYCLAMEN: *D. R., Newton.* The grubs are those of the ordinary weevil. You should take the plants out of the ground or from their pots, shake them free of soil, and plant them again in fresh soil, spraying the roots with bisulphide of carbon. If you find the beetles into which the grubs turn after a while, group the plants in pots all together on a greased sheet of paper, and at night come suddenly into the house where they are with a bright light. This will cause any insects feeding on the leaves to drop off, and they can then be destroyed.

JERUSALEM ARTICHOKE AND SUGAR BEET: *Ignorance.* The tops of the Jerusalem Artichokes may be cut off and burned. The roots are perfectly hardy, and frost will not injure them, but if the soil is water-logged in winter there is a danger of their rotting. The tubers may be lifted, placed in a heap, and covered with fine soil to make a pile. The Sugar Beet may be lifted and stored in dry soil or sand, as in the case of the Red King.

KEEPING FRUITS AND POTATOES: *C. P.* Apples keep best in trays in a frost-proof fruit chamber. Pears the same, but they will not keep long after they are ripe. Plums cannot be kept many days after they are ripe, unless in a refrigerating store, and they quickly rot after being taken out. Grapes keep best on the vines. Nuts should be spread out thinly on the floor of a loft. There are numerous varieties of Apples and Pears which keep over Christmas, and some Apples keep till March or April, including Bramley's Seedling, Newton Wonder, and Dumbow's Seedling. Any fruit nurseryman's catalogue will give you lists of varieties of Apples and Pears which will indicate keeping qualities. All Potatoes keep best in clamps, covered with straw and earth, with a wisp of straw or a drain-pipe on one side of the clamp near the top to act as a ventilator.

LONDON MANURE: *Enquirer.* If you will send us your name and address, we will give you the name of a firm which will probably be able to supply you with manure from London.

MELBA PIG ON VINES: *E. C.* As you cannot obtain methylated spirits, try the following specific: Take one part coal tar and six parts clay; dry the clay and powder it so that it may be passed through a 4 inch sieve. Work the tar and clay together thoroughly, adding sufficient boiling water to make the mixture of the consistency of paint. The specific should be smeared on the vines, filling all the crevices, but avoiding coating the buds. The best method of destroying mealy bug on vines is that of fumigating with hydrocyanic gas.

MITRARIA COCCINEA AND GURISIA COCCINEA: *T. J. H.* *Mitraria coccinea* may be grown in pots, but it needs a cool, shady situation. The soil should consist of moderately close, fibrous peat, mixed freely with sand. The flowers are scarlet, about 1½ inch long, and are developed singly in the axils of the leaves on pendent, slender pedicels. The leaves are small, ovate in shape, and serrated. *Gurisia coccinea* has also scarlet blossoms, and they are about the same length as those of *Mitraria*. The spike grows from 6 to 12 inches high, and bears about 3 or 10 drooping tubular flowers. The plant is best grown as a ground creeper in a cool house. Shade is necessary, for hot, dry conditions are fatal to success.

NAMES OF FRUITS—In the naming of fruits, we desire to oblige our correspondents as far as we can, but the task would become too costly and too time-consuming were there no restrictions. Correspondents should observe the rule that NOT MORE

THAN SIX VARIETIES be sent at any one time. The specimens must be good ones; if two of each variety are sent, identification will be easier. The fruits should be just approaching ripeness, and they should be properly numbered, and carefully packed in strong boxes; cardboard is often smashed in the post. A leaf or shoot of each variety is helpful, and in the case of Plums, Peaches and Nectarines, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. By neglecting these precautions, correspondents add greatly to our labour and run the risk of increased delay and incorrect determination. We do not undertake to send answers through the post, or to return fruits. Fruits and flowering plants must not be sent in the same box. Delay in any case is unavoidable.

F. W. H. Norfolk Beefing.

NAMES OF PLANTS.—Correspondents not answered in this issue are requested to be so good as to consult the following number.

B and Son. *Cyprissus macrocarpa.* — *F. S. M.* 1, *Cypridium insigne*; 2, *Cypridium Harrisonianum* (villosium × bartianum); 3, *Cypridium nitens* (insigne × villosium), which may have been imported or home-raised. — *E. E. S., Bath.* 1, *Francoa appendiculata*; 2, *Browallia elata*; 3, *Nephrolepis exaltata.*

POTATO SALE: *H. P. W.* The farmer or grower requires no licence to sell Potatoes grown by him. Clause 4 of the Potatoes Order, 1917, states: "Except a grower selling his own Potatoes no person shall after September 30, 1917, sell Potatoes by wholesale either on his own account or as agent on commission unless he is entitled to and has applied for registration as a wholesale dealer, or by retail unless he is entitled to and has applied for registration as a retail dealer under Part II. of this Order, and except a grower selling his own Potatoes, no person shall after October 31, 1917, sell Potatoes by wholesale either on his own account or as agent on commission unless he holds a certificate of registration as a wholesale dealer under Part II. of this Order for the time being in force or by retail unless he holds a certificate of registration as a retail dealer under Part II. of this Order for the time being in force. Provided that this clause shall not prevent a wholesale dealer from selling direct to consumers in quantities of not less than 1 cwt." Thus the farmer or grower requires no licence to sell Potatoes grown by him. But a dealer requires to obtain a licence him.

RASPBERRIES AND CURRANTS: *Ignorance.* These small fruits may be planted in favourable weather, but if the ground is cold with frost delay the work until the ground is warmer. If the Currant plants are lifted with a good ball of soil at the roots and planted immediately, they will doubtless bear satisfactorily next season, but in the case of the Raspberries, cut the canes down to within one foot of the ground, to encourage the plants to develop strong suckers next year.

"STINGFOLLOW" METHOD OF PLANTING FRUIT TREES: *F. T.* This method is well known in America, and a book on the subject has also been published in France, entitled *La Pomologie Nouvelle*. Experiments made in Kent have succeeded well. The method should be called the "Laurence" method, as the Rev. J. Laurence practised and recommended it in Tudor days.

TREE STUMPS: *J. G.* There is always a possibility of fungous diseases spreading from decaying stumps to young trees newly planted in ground that was occupied by old trees. As a rule the fungus enters the injured roots of the fresh trees, the spores and mycelium of the fungus finding an easy means of entry through the wounds. Uninjured roots and branches are, as a rule, safe against attack. You need not fear any serious trouble in the case of the trees you mention.

Communications Received.—*Sir H. V.—T. W. B.—W. A. H.—H. G. E. W. T.—G. Henslow.—T. S. M.—Laverpool.—J. S.—E. T. Humphreys.—W. F. R.—B. E. F.—J. A. B.—W. T. Coppl. White.*

MARKETS.

COVENT GARDEN, December 22

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—Eds.

REMARKS.—The severe weather is reducing the supply of cut flowers for the Christmas trade. The supply of Arums is limited; prices are already much higher. Very high prices are likely to be maintained for our nations during the next few days. Lily-of-the-Valley, on the contrary, is more plentiful and lower in price than for some weeks past. Circumstances point to the supply of Chrysanthemums being limited, and high prices are likely to be made for good spray white and hybridized blooms. Spray yellows appear to be the most plentiful in household kinds. There is no guarantee as to the arrival of French flowers during the next few days. A few pads of paper white Narcissus and bunches of scarlet Ranunculus are fetching high prices. Parma Violets also find a ready sale immediately they arrive. Poinsettias, scarlet Pearlgoniums, and scarlet Carnations are the leading lines in "scarlet" offered for the Christmas trade. Tulips, early Daffodils, and several other flowers will be in season this year, and there will not be much selection for buyers. Several boxes of Christmas Roses are being received in good condition.

Vegetables; Average Wholesale Prices.

— Almerias, per barrel (14 doz.)	4 0-50 0	Pears, per 1/2 bus.	120 150 0
— Canon Hall, per lb.	2 0-2 6	Tomatoes, English per 12 lbs. or less	12 0-20 0
— Gros Colmar, per lb.	1 6-3 0	Walnuts, French (greenable), per long (16 lbs.)	18 0-20 0

REMARKS.—The supply of English Apples is plentiful. Britain's seedling, Diamond's Seedling, and Blenheim Pippin especially. American dessert varieties a fair supply of Cox's Orange Pippin is available. Pears now available are the Worcester and Easter Parrot. Fair supplies of Gros Colmar, Black Alicante, and Muscat of Alexandria are available. Nuts, oranges, lemons, and pears are comparatively scarce, and after the week there will probably be no more. Tomatoes, the following foreign vegetables are available: Scotch Asparagus, Peas, Dwarf Broad Beans, Peas, Broadbeans, and Kidney Beans. There is very little of these as a rule. Apples, both English and French, and flowers are limited in supply, but other outdoor vegetables are plentiful. F. H. R., Covent Garden Market, December 22, 1917.

IN PRAISE OF THE GARDENERS' CHRONICLE.

THE GARDENERS' CHRONICLE

is the only gardening paper with seventy-six years of history behind it. It was founded in the dawn of what is commonly termed the scientific age. It has seen the rise and development of the railway, and its partial supersession by motor road-traffic; the discovery of the power of electricity, and its application to a bewildering multiplicity of every day affairs; the economic emancipation of women, and their entry into industrial life; and, last of all, the discovery of the flying machine—so long believed to be impossible. The GARDENERS' CHRONICLE has not remained static through all these marvellous changes. It has grown, developed, expanded. It has remained throughout its whole career completely in sympathy with its readers. It has advanced with them, explored with them the realms of experiment, examined with them in a spirit of intelligent sympathy every new theory of botanic or horticultural science, provided a medium whereby they have been enabled to communicate with each other and make their discoveries known. It has recovered for its great age, yet respected for its modernity; it has the experience of years and the elasticity and progressiveness of youth. Through the storm and stress of the past three years it has stood unmoved, and it looks forward in full confidence to the enjoyment of the ampler scope and increased opportunities which the termination of the war will bring.

AN ADMIRER.

By Special Appointment to

His Majesty The King.

MACKENZIE & MONCUR, LTD.,

HOTHOUSE BUILDERS,
HEATING AND ELECTRICAL ENGINEERS, etc.

Although we are at present employed largely on National War Service, we are still in a position to carry out urgent private work. We ask our patrons to give us as much time as possible for the carrying out of such work, so that we may arrange to have it done without reducing our War Service output.

ROSES—ALLEN'S GOLD MEDAL NORBRIK ROSES our new descriptive paper No. 1411 is on How to Grow Roses, new 1918, published. Write to **A. J. & C. ALLEN, Rose Growers, Northwick Road, W. 10.**

THERE is no more delightful occupation for the long evenings of winter than reading to make up a good fire, and take in one's hand a "Gardeners' Chronicle," this represents the name of comfort, even a hard day's work in reading, as in every thing else, it is "everyone to his taste," and the garden enthusiast, be the professional or amateur, will choose for his winter evenings a book which deals with the subject nearest to his heart that of horticulture. And on this theme, old yet ever new, no volume can give so much and such varied information within a short compass as a bound volume of the "Gardeners' Chronicle." In one page it tells of the latest discovery in horticultural science, and describes the rich harvest of new plants introduced into cultivation by intrepid plant collectors from the remotest parts of China and Tibet. On another page it relates the progress of the horticulturists of to-day in the raising of new plants by hybridation, and, again, it tells the romantic history of the latest recruit to the legion of plant pests. The "Gardeners' Chronicle" has been printing such facts for over seventy years.

TO THE TRADE. COOPER TABER & CO., LTD., 30 and 32, Southmark Street, London, E.C. 4, send their Wholesale Catalogue of Seeds to all who request it. If no preserved envelope copy will be sent on application.

PRIVATE.

GARDENER (HEAD) or Gardener and Small Estate Management where required. The experience in all branches, inside and out; early and late leaving; several years' Head in good gardens; thoroughly reliable. Highly recommended, married (no children).—WOODHURSE, Posingworth Gardens, Cross in Hand, Sussex.

GARDENER (HEAD), in good establishment; life experience England and Scotland, 13 years in present situation as Head, excellent references; married; age 48, family two. State wages.—HAWKE, Riviera Palace Gardens, late Polwarthen, Penzance, Cornwall.

GARDENER (HEAD); well up in all branches and life experience; 3 years present, long service previous; age 45; married 12 boys, home, 14 and 11.—W. VEALE, Cranage Hall Gardens, Holmes Chapel, Cheshire.

GARDENER (UNDER); good all round knowledge, inside and out; age 21; Army discharge; 3 years at Oldbells Hall, excellent references; seeks re-engagement; both preferred. Write, stating wages, &c., to WM. BRIGAN, 2, London Road, Burgess Hill, Sussex.

TRADE.

ADVERTISER seeks re-engagement as MANAGING CLERK, age 45, lifelong experience in Nursery and Seed Trade, Accountancy, Book-keeping, and organization—formerly distinguished seed credentials.—"JANUARY," Box 25, 41, Wellington Street, Covent Garden, W.C. 2.

CLIMBING PLANTS

(Present-Day Gardening Series)

By WILLIAM WATSON.

(Introduction by William Robinson.)

A Practical Handbook on the Treatment of Climbing Plants, both hardy and tender species. Illustrated with 24 full page plates, 8 of which are reproduced in colour.

Price 2/10 post free from:

The PUBLISHING DEPT., 'GARDENERS' CHRONICLE' OFFICES, 41, Wellington Street, Covent Garden, W.C. 2

THE BOOK OF THE MOMENT. Root & Stem Vegetables

By ALEXANDER DEAN, V.M.H.

At the present crisis the food problem bulks largely. The question of which vegetables contain the most food is a pressing one, and it is found that root and stem vegetables, such as Potatoes, Carrots, Turnips, and Parsnips, contain much higher percentages of food value than green vegetables, valuable though these are as adjuncts.

"ROOT AND STEM VEGETABLES"

is a book which treats only of those vegetables the root or stem of which is eaten, and is therefore especially valuable to all who are endeavouring to concentrate their attention on growing the most economical forms of food. It contains eight coloured plates reproduced from photographs.

NOTES FROM A GALLOWAY GARDEN.—XIV. AND LAST.*

IT would be difficult to find any term in horticulture which covers so many degrees of good, not so good, and bad as "the herbaceous border." Much mischief has been wrought since hardy perennials became the fashion by aiming at effects similar to those produced by bedding out. Now, the decorative character of bedding out was the result of the continuous flowering of certain half-hardy exotics, which ensured a brilliant display for three or four months out of the twelve. Gardeners found that nine employers out of ten were easily gratified by breadths of showy colour, and competition grew keen who should produce the brightest blaze. But the system held within it the seeds of transition. It excited the eye, but left the imagination cold. Neither interest nor association could attach to plants that had to be flung on the waste heap after the first frost, and the sweet of the year was robbed of part of its charm when every garden was drilled into servile repetition of a hundred others. Wherefore, when Mr. Robinson raised the standard of revolt in the early seventies, an eager band of reactionaries rallied to him, which now includes practically everyone who takes an understanding part in the ordering of a flower-garden.

But whereas it is not every owner of a garden who has either leisure or knowledge

* Previous articles appeared in the issues for Jan. 15, Feb. 17, Mar. 10, April 14, April 28, June 2, June 30, July 21, Aug. 18, Sept. 8, Sept. 29, Oct. 20, and Nov. 19, 1917.

to apply to the cultivation of flowers, the management and arrangement of hardy perennials must be left in most cases in the hands of professional gardeners, and it is to that class that I venture, greatly daring, to address a word of warning, lest the blight of monotony, which killed bedding out, should prove as deadly to the flower gardening which has taken its place. Bedding out, with all its monotony, was never dismal; but dismal effect is inevitable if the present tendency to treat hardy perennials in the formal arrangement appropriate to bolders gains ground.

And they are being so treated in certain large gardens. "Come and look at my herbaceous border," said a lady to me recently. It was certainly, to use a colloquialism, "very fine and large." It was about 140 yards long, straight as a line could lay it, and devoid of a single feature to vary its shadowless uniformity. Every half-dozen yards of it was an exact replica of every other half-dozen—a clump of Asters, of Torch Lily, and Helianthus in the back row, with plants of descending stature arranged with mathematical precision towards the front. Examination of the first few yards left one without any inducement to go further. True, it was chill October; Asters glimmered uncertainly amid tarnished Torch Lilies and the Helianthus flashed a few stars over the dreary scene; no doubt there may have been plenty of colour in July, but none of the mystery—none of the surprise—which enhance the attraction of a well-chosen collection. Neither was there any suggestion of permanence, which is one of the chief merits in hardy perennials; to maintain the rigid discipline prevailing in this border, these herbs must be taken up and replanted so soon as they betray the least tendency to liberty.

Let me cite another example. This time it was not long past midsummer; to describe the weather of the time tempts one to borrow from that master of perverse phrase, Lewis Carroll:

'Twas brillig, and the slithy toves
Did gyre and gimble in the wabe;
All mimsy were the borogoves,
And the mome raths outgrabe.

It was an old Scottish garden, four-square and spacious within lofty walls of red sandstone. Everything was rectangular; broad grass walks crossed at right angles in the centre and the flower beds were but wide strips of border in front of the kitchen stuff. Not a romantic design, you will say; and, indeed, there was no straining after effect; but age had so dimmed the intrusive line of the masonry, ancient, moss-grown Apple trees broke so tenderly the border-lines, casting cool shades across the paths; there were such fascinating nooks within the ample space, with here a choice shrub and there a breadth of Bell-flower or scarlet Lychnis, that the critic of garden design should have been dumb. The special glory of this garden was the Madonna Lily. It had spread into wide mats, sending up sheaves of five-foot stems, with leaves untarnished by the foul fungus that wrecks so many hopes, and with crowded flower-trusses that gleamed like friendly ghosts in the summer gloaming.

But the place changed hands; a new laird and a new gardener undertook to renovate the grounds; money was freely spent, and when I last saw the garden, gone were the ancient Apple trees; the borders were filled with spoil from distant lands, all scrupulously labelled; and at measured distances among them were the Lilies, broken up into little clumps and withering sadly with botrytis. It will take two generations of men to restore the tranquil beauty of that old pleasure.

Happily, there are many examples of felicitous disposal of herbaceous plants. The first inkling I received of it—fifty years ago, alas!—was in the grounds of the Oxford College so paradoxically called New (it was founded by William of Wyckham in 1380!), and the impression has been revived and checked by hours spent among the borders of St. John's College, so lovingly tended by the Rev. H. J. Bidder, where lofty trees cast slanting shadows across glades of immemorial turf and lowlier treasures lurk in the bays to offer glad surprise to him who strolls into that secluded Eden.

Let it not be supposed that I underrate the attention needed to keep a herbaceous border in condition. To do so requires far more varied knowledge and more constant care than the bedding-out system. But perfection can never be approached if the plants are constantly being shifted. Some of them must be taken up and divided at short intervals if the best is to be got out of them, such as Asters, Chelone and Perennial Sunflowers; but Lilies and many deep-rooting herbs intensely resent removal. The average life-term of forest trees has been pretty accurately ascertained; but who can estimate the duration of a clump of Christmas Roses or Hepatica? It is the permanence of such lowly growths, linking one generation with another, that imparts a peculiar charm to the herbaceous border—a charm that vanishes under the treatment which prevails in some large gardens.

There is, of course, a risk of the enthusiast falling into the other extreme—of cherishing every new exotic simply because it is new and rare. Of the myriad species which intrepid collectors have sent home during the last five and twenty years, the majority are only suitable for a botanical garden, though it is true that in the minority are plants of surpassing beauty and interest.

"All very well," I hear some critic murmur, "but what has all this to do with a Galloway garden?" The rebuke is just. I have wandered from the theme for which I have been accorded space in these columns far out of proportion to the modest demesne that has furnished the notes. The year wanes; the reader perhaps yawns, and I lay down the pen in earnest hope that some fresh hand will take it up and ply it; for it is from records of experience and observation under various conditions of soil and climate that we make progress in the craft that Andrew Lang once described as "a device of Providence for the pottering peace of virtuous old." *Herbert Maxwell, Monreith, Wigtownshire.*

ON INCREASED FOOD PRODUCTION.

ALLOTMENTS IN THE YEAR 1795 AND IN 1917

It is curious how often history repeats itself. The remains of ridge and furrow on common land long ago gone back to grass, yet persisting as an eloquent memorial of the food crisis of the Napoleonic wars, and the present-day turning up of grass land to meet an impending food shortage. Similarly may be found a like historical repetition in the conversion of public parks into vegetable plots. As it was in the year 2 (of the French Revolution: 1795), so is it again now. Then, as now, it was decreed

was reaching France from England, Holland, or Germany. Hence, in order to educate the public it was decided that the public gardens should be converted into allotments, and the flowers replaced by vegetables. It was not that the Committee of Public Safety hoped to feed Paris with the allotment produce, but that it did hope—and the event justified it—that public example would encourage private practice, and that everyone with vacant ground would be led to do for his part what the State regarded as good for all. That officialdom then as now sometimes suffered—or rather caused others to suffer—from excess of zeal is evident from the reproof which was administered at the plaint of "le Citoyen Georget" to the Commissioner of his

Jens. Then, as now, there was a tendency to overdo the planting of Potatos to the exclusion of other vegetables, and then, as now, it was necessary to take steps to prevent pilfering of the allotments; although history does not record that the pilfering went so far in the year 2 as it has sometimes gone this year, when adroit thieves have gone, as it were, tickling for Potatos—running their hands along the rows and picking out the half-formed tubers—a crime of the same order as seething the kid in the mother's milk! The question of seed for the Potato crop was a burning one in the year 2, as it was in 1916-17, but in both cases it was solved in a similar way—by the purchase of seed in districts a long way off.

As a result of the experiment of year 2, many thousands of town bred citizens made the acquaintance for the first time, outside a green-grocer's shop, of such vegetables as Turnips, Radishes and Artichokes. Crowds went to see the Maize and Beans, the Haricots and Lentils, and the rest of the vegetables growing in the Tuileries, and learned from the labels that these things had names like themselves. The war bread of year 2 helped to rub in the lesson, but the description "the crumb is only fit for rabbits," was more flattering than that which has been passed on its modern counterpart.

So as it watched the experiment the Convention grew well content with the results, and judged that the expenditure (12,000 livres for 165 toises) was well spent, for thousands of those who went to see would go home and do likewise. The 1916 repetition was, we fear, less happy; it gave an opportunity for silly questions in the place where they are so often asked; but should these lines meet the eye of the First Commissioner of Works, perhaps he will be emboldened to do on a large scale, and with large labels, what he began to do last year—make demonstration gardens after the model of the Tuileries and Luxembourg allotment gardens of the year 2.

Yet after all, the silly questions were asked by the citizens of year 2. They claimed that this public park gardening was nonsense, asking whether it was not true that a field of Oats was worth all the produce of the Tuileries, and so it will be to the end of things. Men will struggle and subdue Nature, and explain that all innovation is vain, and obstruct—and succeed—"Plus ça change, plus c'est la même chose."

PRIMULA CHIONANTHA.

PRIMULA CHIONANTHA (fig. 98) is a noble species, belonging to the nivalis section. The plant is a native of Yunnan, China, where it was found by Mr. Forrest on the mountains of the Chungtien plateau at an altitude of 12,000 to 15,000 feet, in open, alpine meadows. It is very robust in habit, with a tuft of leathery leaves, each 8 inches or more long, and 2 inches wide at the broadest part, from which are produced the stout stems, rising from 12 inches to 20 inches in height. Like the under part of the leaves, the stems, pedicels, and calyx are coated with a golden meal. Strong stems bear two or more whorls of flowers; those shown in fig. 98 have 27 flowers in each whorl. The flowers are ivory-white, nearly 1 inch in diameter, and produced on drooping pedicels varying from $\frac{3}{4}$ of an inch to 2 inches in length.

Seeds of this plant were received at Kew from Mr. J. C. Williams in 1915, and a good batch of plants were raised. Many of them flowered in May of this year in a shady position, and some plants produced flowers in November. Notwithstanding the vast number of Primulas recently introduced to Europe, *P. chionantha* is likely to prove one of the most popular species. W. L.

FIG. 98.—PRIMULA CHIONANTHA: FLOWERS IVORY-WHITE.

by the Committee of Public Safety, that the borders of the Paris parks, including the ancient Luxembourg Gardens of "Monsieur" and "Madame," should grow not flowers but Potatos and legumes generally.

And when the First Commissioner of Works determined to start demonstration gardens in the Royal parks he was consciously or unconsciously adopting precisely the same procedure, and from the same causes as that adopted on 13th Vendose 1795 by Messieurs Barrère, Carnot, Robespierre, and their colleagues of the Committee of Public Safety with respect to the gardens of Paris.

The world was at war with France. Food was scarce, and but little of the usual supplies

section. The Commissioner evidently was the revolutionary replica of the whole hogger of modern times, and wanted to make Citoyen Georget dig up his fruit trees and grow Cabages instead. Citoyen Georget objected, and the Convention supported his objection, voting penalties against those "evil doing spirits who would tear up a tree in order to plant a—Cabage." Trop de zèle then could, of course, be matched by a like complaint now, and doubtless this defect of the quality of enthusiasm will always remain with us.

Three days after the decree of the 13th Vendose of the year 2, instructions were issued for the conversion of the flower beds at the Tuileries, Luxembourg, and other public gar-

EDITORIAL NOTICE.

Editors and Publisher.—Our correspondents would oblige by delaying in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which they desire to bring under the notice of horticulturists.

Letters for Publication.—As well as specimens of plants for naming, should be addressed to the EDITORS, 41 Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent early in the week as possible, and duly signed by their writers. If desired, the signature will not be printed, but kept as a guarantee of good faith.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, S.E.

ACTUAL TEMPERATURE.—*Gardeners' Chronicle*, 1011, 41, Wellington Street, Covent Garden, London, *Thursday*, December 27, 10 a.m. Bar, 30.2; temp., 36.0. Weather—Fine.

It is a well-established fact that in certain plants—Maize, for example—hybrids produced by cross fertilisation show a marked superiority in productiveness over the parents between which the cross was made.

Hence the suggestion has often been made that it should be possible in the case of food plants which are habitually self-fertilised and are easily cross-fertilised by artificial means, to raise seed each year by cross-artificial fertilisation, and thereby obtain first-generation hybrids which would repay the trouble by their extra yield.

One of the plants which lends itself readily to experimentation along these lines is the Tomato. It is self-fertile, and yet can be easily crossed by artificial means. In ordinary conditions of cultivation it is almost, but not quite, always self-fertilised. In the open, at all events, occasional crosses occur. Hence it might be supposed that this plant, grown year after year from self-fertilised seed, might be all the better for occasional or regular crossing. Against this idea, however, is the striking fact that the yield from the best varieties of Tomato is already remarkably high. It is, for example, not uncommon for Tomatos grown under glass in the Lea Valley and elsewhere to yield so much as 40 tons to the acre, and this amount is said to be exceeded occasionally.

In spite of the apparent improbability of obtaining yet higher yields, it is most desirable that the question should be answered by the authoritative method of experiment. Trials made at the beginning

of the war at Wisley, where the varieties Sunrise and Merivale were crossed with one another, gave only negative results. The hybrid was as good as either parent, but no better so far as yield was concerned. Unfortunately, the trials had to be broken off owing to the exigencies of the war. In the meantime the subject has been taken up independently by Messrs. Hayes and Jones,* with results which cannot fail to be of interest to the Tomato grower.

As a preliminary the yields resulting from self-fertilised seed of selected varieties were ascertained over a period of several years, and it was found that self-fertilisation during three or four years caused no noteworthy diminution of yield. All that happened was that a number of types was isolated, some of which were of higher, and some of lower-yielding capacity. In other words, self-fertilisation gives an opportunity to the grower to select seed from the higher-yielding strains. This, of course, is what good growers already do. But, in spite of the fact that there was no falling-off in yield in self-fertilised strains, it was ascertained experimentally that in the case of some varieties the result of cross-fertilisation was to produce a definite superiority of yield over either parent. Thus in the case of the cross Stone and Dwarf Champion the first-generation hybrid gave a regular 8 per cent. over the parental average. This, in terms of yield per acre, would mean an extra ton and upwards to be obtained at the very slight expenditure of time and trouble required for the work of artificial fertilisation. That operation is of the simplest. When the plants are growing under glass the chance of accidental fertilisation may be ignored. All that is required is that the ring of stamens should be lifted off before they burst. This may be done with the point of a penknife. Pollen from the other parent should be dusted in the stigma of the emasculated flowers which are marked by a coloured thread and left to set their fruits. If absolute certainty is required, the emasculated flower may be covered with a paper bag so as to prevent any pollen other than that of the variety chosen as the male parent from reaching the stigma. In Messrs. Hayes and Jones' experiments with the two varieties already named (Stone and Dwarf Champion), not only did the first-generation hybrid show an 8 per cent. increase in weight over the parental average, but it also produced about the same number of fruits as the better parent, so that producing as many, or nearly as many, fruits as the one parent, and as heavy, or nearly as heavy, fruits as the other parent, the superiority of the first-generation hybrid over the better parent was not 8 but 15 per cent. In the course of the four years during which the experiment was conducted the superiority of the hybrid ranged from 11 to 17 per cent.

It must be borne in mind that the

* *The Effect of Cross and Self-Fertilisation on Tomatos*. Report of the Connecticut Agric. Exp. Station, New Haven, Conn.

hybrid seed must be raised artificially each year, for hybrid vigour only manifests itself to the full in the first generation.

It is also to be remembered that it is not to be expected that any two varieties mated together will inevitably produce so good a result as that yielded by Stone and Dwarf Champion. Thus the authors found that when Lorillard and Best of All were crossed together the hybrid gave no higher yield than that given by the better parent.

No less interesting, and possibly of greater practical importance, is the observation made by Messrs. Hayes and Jones that when two varieties of Tomatos differing with respect to earliness are crossed with one another, the first-generation hybrid is earlier than either parent, whereas in the actual experiment the earlier of the parent varieties (Dwarf Champion) produced 55 per cent. of its crop by a given date, the first-generation hybrid produced 59 per cent. of its crop by that date. The importance of a market-gardener being able to modify in this way the time at which his produce is marketed is self-evident. As the authors point out, the vigour imparted to the hybrid as a result of crossing differs from vigour induced by specially favourable external conditions; for whereas the latter tends to prolong the vegetative and delay the fruiting stage, hybrid vigour hastens the stage of fruit formation.

Messrs. Hayes and Jones have also extended their experiments to Cucumbers, with similar results. The varieties used for the purpose were: Early Russian, White Spine, London Long Green, and Fordhook Famous. In all the crosses the first-generation hybrid exceeded the more prolific parent by an average of from 1.5 to 8 fruits per plant—that is, from 6.27 per cent. The smallest result was obtained from the cross London Long Green and Fordhook Famous, which two varieties are of very similar habit and character. Where, as was the case in the other crosses, the parents differed markedly from one another, the hybrid vigour of the first-generation hybrid was pronounced.

BOTANICAL MAGAZINE.—The following plants are illustrated and described in the issue of the *Botanical Magazine* for July, August and September:—

Pinus tiberi-plata, tab. 8,717.—This species was first illustrated and described by the late Dr. Masters in *Gard. Chron.*, December 19, 1885, p. 795, from a specimen furnished by Mr. Baker, of Bayfordbury, from his Pinetum. A portion of a branch of this tree, bearing over forty cones, is still preserved in the museum at Kew. The native habitat of the species is Western North America, where it is known as the Knob Cone Pine. It was discovered by Haerweg in 1847. The species usually makes a tree 20 to 25 feet in height.

Ophitoglossum platycheilum, tab. 8,718.—This species was illustrated and described in *Gard. Chron.*, May 7, 1892, when the plant received an Award of Merit from the Orchid Committee of the Royal Horticultural Society.

Oreocharis forrestii, tab. 8,719 (fig. 99).—This new Chinese plant was illustrated in *Gard. Chron.*, October 30, 1915, fig. 97, under its

synonym of *Rottlera Forrestii*. It forms rosettes of leaves about 5 inches in diameter after the manner of *Ramondia*, and bears scapes about 6 inches high with yellow, cylindrical flowers.

SINOFRANCHETIA CHINENSIS, tab. 8,720.—This plant has been named *Holboellia cuneata* and *Puryata chinensis*; it is a member of the *Berberidaceae*. It forms a wide climbing shrub, with twining stems; specimens raised at Warley Place, Essex, flowered and fruited in their third year, and proved perfectly hardy. The inflorescence is a long raceme bearing small, flesh-coloured blossoms; these are succeeded by pinkish-mauve fruits about the size of hazel-nuts.

RHODODENDRON CUFFIANUM, tab. 8,721. This species is named in honour of the discoverer, Lady WHEELER CUFFY, who met with it on an elevation of 6,000 feet in Upper Burma. The flowers are white, with a little orange-yellow colour in the throat, and form a bold truss of fragrant blooms.

BERBERIS AGGREGATA, tab. 8,722.—This Bar-

ODONTOGLOSSUM CHIRIQUENSE, tab. 8,725.—This plant has been regarded as a variety of *O. coronarium*, but it is readily distinguished from that species by its larger and very undulate flowers. It is particularly handsome, with rich orange-coloured flowers.

ORESTROPHI RUFIFRAGA, tab. 8,726.—An illustration and description of this plant were given in *Gard. Chron.* for April 14, 1917, p. 155. It is the solitary member of the genus, which belongs to the N. O. Saxifragaceae.

RHODODENDRON NERIIFLORUM, tab. 8,727.—Originally discovered by the Abbé DELAVAY in Yunnan, this charming *Rhododendron* was introduced into cultivation by Mr. G. FORREST. The plant forms a dwarf shrub, flowering when less than 18 inches in height. In the wildings the flowers vary in shade from rose-colour to crimson or scarlet, and provide brilliant patches of colour.

ASTER FUSCENSIS, tab. 8,728.—This plant is a hardy perennial, growing about 2 feet high, and is recommended as a good garden plant. Its

the plant was originally described by Mr. J. G. Baker.

DAPHNE GERALDI, tab. 8,732.—Named after Pere Gerald, who discovered the species in China, this shrubby, dwarf plant has small corymbs of golden-yellow flowers.

PRINUS SUBHIRTELLA, tab. 8,733, var. *autumnalis*, tab. 8,733.—This plant is sometimes met with in gardens under the name of *P. Miqueli-ara*.

MEGACARPAEA POLYANDRA, tab. 8,734.—See *Gard. Chron.*, July 2, 1892, fig. 4, and May 13, 1916, figs. 107 and 108.

PRIMULA NUTANS, tab. 8,735.—See *Gard. Chron.*, May 13, 1916, fig. 110.

RHODODENDRON FARGESII, tab. 8,736.—See *Gard. Chron.*, July 6, 1912, fig. 4.

SARCOCHILUS SOLOMONENSIS, tab. 8,737.—This plant is like a *Phalaenopsis* in habit, but differs greatly in the inflorescence and floral details. The petals and sepals are pale buff colour spotted with brown.

SECHUM EDULE, tab. 8,738.—An old plant in gardens, and one frequently described in *Gard. Chron.* The fruit is illustrated in the issue for December 22, 1900, figs. 144 and 145.

SYRINGA WILSONII, tab. 8,739.—A species closely allied to *S. tomentella*; it is valuable because it flowers later than other Lilacs.

CRYPTOPHORANTHUS DAYANUS, tab. 8,740.—This plant was named *Masdevallia Dayana* by Reichenbach, and is generally known by that name in collections. The openings at the sides of the flowers are known as "windows," which gave rise to the name of "Windowed *Masdevallia*."

GREVILLEA OLEOIDES, tab. 8,741.—A shrub of New South Wales, having leaves in threes and pairs, and racemes of bright carmine flowers.

CO-OPERATIVE MILK DEPOTS.—A scheme for the establishment of a number of Co-operative Milk Depots in England and Wales is being promoted by the Board of Agriculture through the Agricultural Organisation Society.

GARDENING LECTURES FOR TEACHERS.—The Board of Education has circularised education authorities on the importance of training elementary teachers in gardening, with a view to increasing the output of garden produce in the coming year. In consequence of this suggestion special courses are to be arranged during the spring and summer for L.C.C. teachers.

A POTATO-SPRAYING CAMPAIGN.—Afringe' agents are practically complete for the Food Production Department's winter educational campaign in connection with the spraying of next year's Potato crop, and the new scheme for the distribution of Knapsack Sprayers and chemicals will shortly be in operation. The scheme will be worked through the trade. Dr. KEEBLE, the Director of Horticulture at the Department, and Lieut. ASCROFT, the spraying officer, as the result of a series of meetings with the leading manufacturers of Knapsack spraying machines, representatives of the Ironmongers' Federation, the National Association of Implement Dealers, and the Wholesale Hardware Association, have completed arrangements for the widespread and economical distribution of sprayers and materials in good time for next year's campaign. The provisional price of a Knapsack Sprayer is 70s., but it may be necessary to raise this figure in the near future. Arrangements are being made for the manufacture of thousands of tons of the necessary chemicals and for a very large number of machines, but the transport facilities are likely to be heavily taxed in spring and summer, and the sooner buyers get delivery of the goods the better. The price of copper sulphate will probably be Government controlled, and a reduction made on early purchases. The country is being mapped out into county areas for purposes of organisation, with an Organiser and Sub-Organiser in each area, to cooperate with and help the existing authorities.

FIG. 99.—*GREOCHARIS FORRESTII* FLOWERS YELLOW.

berry is one of the numerous new species discovered recently in Western China, and is attractive both in flower and in fruit. It forms a shrub some 5 feet high, and produces congested racemes of flowers, succeeded by clusters of coral-pink berries.

BULBOPHYLLUM THAIENSEM, tab. 8,723. This Orchid has been for a long time in cultivation in gardens in this country, and was included in the collection given by the late Lady LAWRENCE to Kew Gardens. The inflorescence forms a dense spike of rose-tinted flowers, with crimson and purple spots.

POLYGONUM GRIFFITHII, tab. 8,724.—This Knot-weed was discovered in 1857 by Dr. W. GRIFFITH, in Bhutan, but it remained for Mr. G. FORREST to introduce it into cultivation in 1904. Judging by the illustration, the species could make a good garden plant, and as its height is only about 18 inches it would be suitable for the rock-garden. The arching racemes of bright coral-red flowers are exceedingly attractive.

habitat is China, whence it was introduced into this country by Messrs. BEES, through their collector, Mr. F. KINGDON WARD. The inflorescence forms a corymb about 6 inches across; and the stalked flowers make a lax head. The colour of the florets is rosy-mauve.

The following plants are illustrated and described in the monthly parts for October, November, and December:—

PLEIONE PUDICI, tab. 8,729. This new species of *Pleione* is named in honour of Mr. W. F. Price, who, with Mr. H. J. Elwes, discovered the plant in Formosa. The sepals and petals are rosy-lilac coloured; the large, whitish lip is blotched with pale brown, and has yellow ridges.

CASILLEJA MINIATA, tab. 8,730.—This old garden plant was illustrated in *Gard. Chron.*, July 8, 1916, fig. 4, from a specimen in Mr. Elwes' garden. Mr. Elwes gave an account of its history and cultivation in "Notes from a Cotswold Garden" in the same issue.

ORPHROSANTHUS CHIMBORACENSIS, tab. 8,734. See *Gard. Chron.*, 1876, Vol. VI., p. 67, where

THE KITCHEN GARDEN.

By J. DUNN, Foreman, Royal Gardens, Windsor.

FRENCH BEANS.—A sowing of French Beans may be made now with good prospects of the plants yielding a successful crop. The plants will not be in flower until the days lengthen considerably. Large pots should be carefully crooked and filled to within 3 inches of the rim with a rich compost, which may consist of three parts loam from an old Melon bed, and one part old Mushroom-bed manure. Make the compost moderately firm with the hands, and sow a sufficient number of seeds in each pot to ensure a full crop, as it is an easy matter to remove a plant or two if they are too numerous. Place the pots in a house having a temperature of 60°, and when the plants are well through the surface expose them fully to the sunlight. When growth is sufficiently advanced a top-dressing of rich soil may be applied, and a few twigs placed in each pot to keep the growth in an upright position. Syringe the foliage twice daily in favourable weather, and give frequent applications of weak liquid manure from the farmyard. The Belfast is an excellent Bean for forcing.

CUCUMBERS.—Young Cucumber plants raised from seed sown at the beginning of the present month should be carefully potted in 4-inch pots before they become stunted. Put lightly placed in a small stick to each plant, and plunge the pots in a gentle bath within 18 inches of the roof glass. Leaf mould and rich loam in equal parts will form a suitable rooting medium. Cucumber plants which will furnish fruits through the remainder of the winter require very careful attention in regulating the growth. Very little stopping of the plants will be necessary, but the growth must never be allowed to become crowded. Remove all rough leaves and deformed fruits, and only leave sufficient fruits on the plants to keep up the supply. Top-dress the roots lightly as often as young roots show through the surface, as this is the best means of promoting healthy growth. Maintain a moist atmosphere, and when water is necessary at the roots let it be given in sufficient quantity to moisten the whole of the soil. The temperature should be 70° at night in mild weather, rising to 80° by day with sun heat. In very cold weather the temperature may be allowed to drop 5°.

CARROTS IN PITS.—As soon as young Carrots are through the surface soil the lights should be opened to admit air. Examine the bed, and, if necessary, water the soil with rain water through a fine rose. Keep a close watch to slugs, which would soon ruin the plants. Successional sowings of Carrots should be made to maintain an unbroken supply of roots.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLEMAN, Bart., Ganton Park, Beigate.

TRICHOPILLIA.—The various species of *Trichopillia* flower at different times of the year, and, for that reason, their potting should be carried out at intervals, the proper time being when roots begin to develop from the base of the new pseudo-bulbs. *T. sauis* is the most handsome species, and is most commonly grown. *T. coccinea*, *T. tortilis*, *T. sanguinea* and *T. Backhouseana* are other good garden species. Most of the plants have finished growing, and must not be watered so frequently as hitherto, or their pseudo-bulbs and leaves will soon become spotted. So long as the pseudo-bulbs remain plump very little or no water is required, but if they show signs of shrivelling a moderate amount of moisture should be afforded the roots. During their resting period the plants should be suspended near the roof glass in a dry position in the intermediate house. Expose them to the light, but provide shade from direct sunshine; rather deep Orchid pans form the best receptacles in which to grow them. *T. fragrans* is a white, sweet-scented species, and is now showing its flower spikes. The

plant thrives best in the warmest part of the Odontoglossum house.

MILTONIA.—Plants of *Miltonia vexillaria* and its hybrids are growing freely. Sufficient water should be given to keep the Sphagnum-moss on the surface in growth. An intermediate temperature is most suitable to these Orchids in winter, as the compost will not become dry quickly in a house where little fire-heat is employed. Stand the plants in a light position and allow them to develop their growths steadily. The young leaves frequently adhere to each other, and should be separated by means of the thin part of the handle of a budding-knife. A brown, damp-looking outer sheath at the base of the young growth often clasps the stem so tightly that the roots push upwards instead of growing into the compost. This brown covering should be slit in several places and removed in small pieces, without causing injury to the plant. If the leaves show signs of damping at the tips give the roots rather less water and ventilate the house rather more freely. The foliage should be sprayed on all favourable occasions to keep down attacks of insect pests. The above remarks apply also to *Miltonia Bleiana* and its hybrids.

THE HARDY FRUIT GARDEN

By W. A. COOK, Gardener to the Hon. ARTHUR J. DAVEN Abbas Wood, Godalming, Surrey.

GENERAL REMARKS.—If the weather continues frosty make a large garden-fire to burn tree prunings and rubbish. When the base of the fire is red-hot place on all rakings and weeds from the fruit quarters. These latter will smoulder, and there will be no risk of a blazing light at night, which is prohibited in these times. When thoroughly burned the whole mass should be turned and mixed together; it will form useful material for future planting and top-dressing. Composts should be got ready, mixed and turned several times in a dry shed; stakes of all kinds and sizes prepared, and labels tied in bundles. Large stakes should be stripped of the bark and either painted or treated with creosote. Shires should be cut in lengths and afterwards soaked in a nicotine preparation to prevent insects lurking in them. Tools should be ground or otherwise sharpened. The store-room should be put in order at least once a year and the stock taken. Walls may be whitewashed, nets overhauled, and notes made of anything that will be required for next season.

THE FRUIT ROOM.—Fruit required for current use should be handled carefully, and taken from the fruit room in a covered basket to a warm atmosphere 24 hours before being sent to table for dessert. Carefully look over all fruit and remove any that are the least specked. Make notes of the keeping qualities of various fruits, especially of new varieties.

FRUITS UNDER GLASS.

By JAS. HUTTON, Head Gardener at Gunnersbury House, Acton, W.

POTTING LOAM. A plentiful supply of good loam is essential in almost all phases of gardening, and in none is it more needed than in fruit culture under glass. I prefer to renew the stock of loam at this season of the year, if the weather is open. Trimmings from the road sides in country districts furnish a good material for adding to the main bulk of loam obtained from heavy loam, being sharp and zesty. Caution in the use of this material is, however, needed, now that tar is used to lay dust. I have had no difficulty in obtaining good loam for years past. For fruit culture choose a calcareous loam with plenty of fibre in it. If the soil be too heavy or retentive, add road scrapings in making up the stack. Old mortar rubble is a valuable material for adding to the loam in preparing special composts. Stack the loam where rains will not permeate it and make it sodden. The soil yard should be open to light and air. A few cart loads of well-decayed farm-yard manure should be sown whenever it is possible, and it should be stacked in such a manner as to throw off rains. A calculation should be made as to the requirements for another sea-

son with respect to the quantities in any given case. Do not make shift with soil that is known to be of inferior quality.

LEAVES FOR HOT-BEDS.—Where fallen leaves are required for making hot-beds a supply should be secured and stacked, but not in large heaps, or they would ferment and lose their heat. Oak and Beech leaves are the best. Now that stable manure is not so plentiful as formerly leaves should be made the most use of. Where early varieties of Figs, such as St. John's, are being forced for the first early crop, the leaves will prove useful at once. I stand the pots on a bed of leaves for the first few weeks, and when fresh growth is plainly in evidence plunge them lightly in the leaves. Fallen tree leaves, spread over the surface of inside vine borders, will help to create a genial atmospheric moisture. In no case do I advise their use for either Peaches, Nectarines, Plums or Cherries, for these fruit trees require a somewhat drier atmosphere.

PLANTS UNDER GLASS.

By J. G. WISDOM, Gardener to Lady Northmore, Eastwell Park, Kent.

FREESIAS.—Early plants of *Freesia* are in bloom, and the house should be kept somewhat cooler, as the flowers develop. Successional batches should be grown in a light position and allowed plenty of room for the foliage to develop steadily. *Freesias* do not require much water before they have made considerable roots. Plants that were potted at a late date should be kept in frames for the present for flowering late in spring.

EARLY-FLOWERING GLADIOLI.—The corns of early-flowering *Gladioli* should be potted or planted in boxes as soon as they come to hand. If the spikes are required especially as cut blooms answer admirably, and there is saved a lot of labour. As decorative plants *Gladioli* should be grown in 4½ to 6 inch pots. The compost should consist of two parts turfy loam and one part leaf-mould, with sharp sand added. Place a little sand under the base of each corn, arranging six to twelve of the latter in each pot, according to their size. Leave a good margin of room in the pot for watering. *G. Colvilei* The Bride will furnish a good quantity of white flowers. Other excellent varieties for pot culture are Queen of Holland, Delicatissima, Crimson Queen, Pink Perfection, Ackermannii, and Rosy Gem. After the plants are potted, place them in a cool frame on a layer of ashes, and cover the tops of the pots with Cocoa nut fibre refuse or fine leaf-mould. The corns will quickly start into growth, and later the covering material may be removed. Only a little water is required at the roots until top growth is well advanced. Introduce fresh batches in gentle warmth as required. Give similar treatment to that recommended for *Freesias*.

THE FLOWER GARDEN.

By W. J. GIBB, Gardener to Mrs. DEMSTER, Keble Hall, Staffordshire.

PROTECTING PLANTS AND SHRUBS.—Many plants and shrubs need a little protection from severe frosts and cutting winds; but in open weather only slight coverings are necessary. Tufts of dry Bracken placed round the stems and bases will carry many plants safely through very cold weather. Branches of Yew or Spruce may be placed around the heads of shrubs in exposed situations. In very cold districts *Olearias*, *Buddleia madagascariensis*, *Cordylines*, *Andromedas*, *Eupatorium Weinmannianum*, *Phoradendrons*, and *Toxarium botanicum* should have protection of this description. *Tiffany* forms a suitable covering for wall plants, as it can be removed quickly during a spell of mild weather. *Magnolias* should not be exposed to cold winds, which are often more injurious to them than frosts. Place tufts of Bracken amongst the branches of climbing and standard Roses, and Yew for Tea and other dwarf Roses. Give a mulching of stable litter or leaves to all newly-planted trees and shrubs. Place half-decayed leaves round the bases of tender Alpine and herbaceous plants, with the exception of *Delphiniums*, *Phloxes*, *Gypsophylas*, and *Hollyhocks*; for these, sifted ashes will afford sufficient protection.

ON THE BOTANY AND PHYSICAL GEOGRAPHY OF THE HOLY LAND.

(Continued from p. 247.)

TREES OF SYRIA AND PALESTINE.

Nothing shows the delicate gradations of climate better than the trees, which are above ground all the year and have to bear both the winter cold and the summer heat and drought. The trees of the Holy Land are as follows:—

There are nine species of Tamarix, of which that most familiar to us in England (*T. Gallica*) is not one. They are mostly confined to the coast of Southern Palestine and the lower part of the Jordan valley. There are no Limes (*Tilia*), and the Horse Chestnut, which is wild in the mountains of Greece, is also absent. There are three species of Maple, *Acer lycanum*, *Monspensulanum*, and *syriacum*, the two first confined to the northern hills. *Pistachia vera* is commonly cultivated for its nuts, and is probably wild in the Lebanon district, and the Terebinth (*P. Terebinthus*) and its variety, *Palaestina*, are common from north to south. These have compound leaves, like an Ash. Next to the Gall Oak the Terebinth is the commonest tree in the hills. Holly has been found lately in one place on Mount Amanus. *Moringa aptera*, a sub-tropical type from the seeds of which oil is extracted, is confined to the Dead Sea and Sinaitic peninsula. The Carob (*Ceratonia siliqua*) is everywhere common, reaching a height of 50 feet, and swine are fed on the husks. The Judas tree (*Cercis Siliquastrum*) is common in rocky places, flowering before the leaves open in April. There are six *Acacias*, but these, like the *Moringa*, are almost confined to the Dead Sea and southern desert. The Almond (*Amygdalus communis*) is common, both wild and cultivated. The Plum is said to be wild in the northern mountains, and the word Damson is derived from Damascus. Apples and Pears do not succeed well, but there is a wild Pear (*Pyrus syriaca*) which is sometimes eaten. The Rowan tree is absent, but three other species of the same subgenus (*Sorbus Aria*, *terminalis*, and *trilobata*) are found wild in the northern hills. The Medlar (like the Quince) is cultivated, and is said to be wild in Samaria. There are four species of *Crataegus*, of which monogyna, our English Hawthorn, and *Azarolus*, with a haw as large as a Cherry, are common. The place of the Lilac with us in gardens is filled with the Persian Lilac, *Melia Azadirach*. The Elder (*Sambucus nigra*) is cultivated, and a drink used in fevers made from its berries. *Adiantum Uredo* and *Andrachne* are both frequent. There are three species of Ash (*Fraxinus excelsior*, *oxycarpa*, and *Ornus*), confined to Lebanon and the northern hills. The first and last reach a height of from 50 to 60 feet. The Olive is cultivated everywhere for the sake of the oil from its fruit, and is found wild among the northern hills. The Bay Laurel is common, like the Myrtle, from the coast to the middle zone of the mountains. The Silver Berry (*Elaeagnus hortensis*) is common, both wild and cultivated. Our common Elm is confined to the extreme north, about Aleppo and Aintab, *montana* being unknown. *Celtis australis* (the Hackberry, or Nettle tree) is common in cultivation as a shade tree, and is wild among the northern mountains. The Black and White Mulberry (*Morus nigra* and *alba*) are both commonly cultivated. *Ficus Carica* (the Fig of commerce) is common, both wild and cultivated. *F. sycomorica* (the Sycamore into which *Zarbuscus flumbosus* is a common shrub-tree in the south. The Baywan and Indiarubber are both sometimes cultivated. *Platanus orientalis* is common, ascending to the sub-alpine zone of the mountains. The Walnut (*Juglans regia*) is everywhere cultivated for the sake of its nuts and timber. An Alder, "Abraham's Oak," near Hamme, of which Sir J. D. Hooker gives a sketch, has a trunk with a girth of 25 feet, and a crown

with a diameter of 90 feet. In the winter of 1856-57, when the snow lay for many days in the streets of Jerusalem, a branch of this was broken off. Mr. Finn, the Consul at Jerusalem, wished to have this, but owing to a superstition that anyone who cut it would lose their firstborn son, had great difficulty in getting anyone to saw it up. Finally this was done, and several camels were loaded with the wood of this single limb. It is valued alike by Jews, Christians, and Mahometans. It extends to Spain and Portugal, and is the commonest tree in the hill region of Palestine.

Ahus orientalis is common on the banks of streams. Two Hornbeams (*Carpinus duensis* and *Ostrya carpinifolia*) are found wild amongst the northern hills. Our common *Corylus avellana* is found wild in Cassius and Amanus, but does not reach further south. There are six Oaks, of which two, *Quercus coccifera*, *Q. aegætopis* (the Valonia Oak), of which the very large acorns are used by tanners; *Q. Cerris*, and *Q. lustrantica* (*infectoria*) are less common. *Q. Ilex* is confined to the Syrian coast, and of the British *Q. sessiliflora* there are two varieties in the woods of the middle zone of Lebanon. The Beech (*Fagus sylvatica*) is wild in the middle zone of Amanus, but the Sweet Chestnut, which might probably be introduced with advantage, is absent, although it extends from Europe to Japan and the Himalayas. There are eight Willows, of which *Salix alba* and *fragilis* are frequent, the Egyptian *S. Salsaf* is confined to the sub-tropical zone, and *S. caprea* and *nigricans* are rare in the north. *Populus alba* is common, *P. nigra* and *pyramidalis* are rare, and *P. euphratica* common on the banks of the Jordan and other lowland streams. The Cypress is wild in the middle zone of the mountains, and the congested variety is often, as in the Mediterranean regions, planted in cemeteries. There are five Junipers, of which the common European *J. communis* is not one. The Yew is found only on Mount Amanus. There are two Pines, *Pinus Pinea* and *halapensis*, both common, but *P. sylvestris* is absent. *P. Pinea*, as in Italy, is often trained into the umbrella shape so familiar to us in Turner's pictures. The Cedar of Lebanon is not, as is often supposed, confined to the sub-alpine zone of Lebanon, but occurs also on Amanus and many of the mountain ranges of Asia Minor. The Larch is unknown. *Abies cilicica*, allied to the Spruce, forms forests in the sub-alpine zone of Lebanon and Amanus, reaching a height of 60 or 80 feet. The Date Palm is cultivated in the south of Palestine, and ripens its fruit at Jaffa. The celebrated Date Palm groves of Jericho have been destroyed. The Egyptian Doum Palm (*Hyphaene thebaica*) is found in a few places in the Sinaitic peninsula, but does not reach the Dead Sea or the Jordan valley.

It will be seen that the common trees of Britain and Central Europe are, with slight exceptions, only found in the middle zone of the mountains of Syria, and do not reach Palestine, and that in Palestine their place is filled by more southern types, many of which have a wide range in Southern Europe.

FERNS OF SYRIA AND PALESTINE.

Nothing can well show more forcibly the difference there is in climate between Britain and Palestine than the presence and distribution of the Ferns. The Filmy Ferns are entirely absent as are also the Woodstias. *Cystopteris fragilis* is frequent on Lebanon and the northern hills. *Pteris aquilina* is common up to 6,000 feet on Lebanon. *P. longifolia*, a cosmopolitan species, that does not reach Britain, is common on the banks of streams. *Lomaria Spicant* is confined to Lebanon and the northern hills. *Scelopendrium vulgare* is common up to the alpine zone, and the Mediterranean *S. hermonitis* is confined to the middle and alpine zones of the Lebanon range. *Adiantum Capillus-Veneris* is common in damp caverns and about the mouths of wells. *Cheilanthes fragrans*, common throughout Southern

Europe, is frequent in the clefts of limestone rocks in the hill region. Of the *Asplenium*, *Trichomanes* and *Adiantum-nigrum* are common. *Bourgaei*, *Ruta maritima*, and *septentrionale* are on Lebanon and Amanus. The Lady Fern is not known south of Amanus. *Ceterach* is frequent amongst the limestone hills. *Polystichum angulare* is confined to the northern hills. *Louchitis*, of course, like *Allosorus crispus*, is entirely absent. Of the *Lastræ* there are only three. *Filix-mas* and *rigida* frequent amongst the limestone hills. *Thelypteris*, rare on the anti-Lebanon. *Oreopteris*, *dilatata*, *spinulosa*, *recurva*, are absent. Of the *Polypodium*, *vulgare*, which is the only species, is common on shady rocks. *Notholaena lanuginosa* occurs at Nazareth and around the Sea of Galilee, *N. marantæ* only on the limestone rocks of Cassius and Amanus. *Gymnogramme leptophylla* is associated with *Adiantum* in caves along the coast. *Osmunda* grows in damp woods of the middle zone of Lebanon. *Oploglossum vulgatum* has been found in grassy pastures on the anti-Lebanon. There are no *Lycopodiums*. *Selaginella denticulata* is found on rocks along the coast. And, finally, there are also two *Equisetums*, *Telmateia*, and *ramosissimum*, both common.

This gives us 23 Ferns for Palestine and Syria, against 62 for Britain. Of the 23, eight species are unknown in Britain, of which all but one are widely dispersed throughout Southern Europe. *J. G. Baker, F.R.S., Kew.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

DUTCH BROWN BEANS.—I was most interested in the remarks of *G. H. H. W.*, on p. 216, on Haricot and other Beans, and especially the Dutch Brown Bean. Since that date the R.H.S. has sent out to its Fellows a very favourable report on this Bean, including its analysis. As regards weight of crop, I can record a much heavier yield than *G. H. H. W.*. He gives his crop as 27½ pints from ¾ pint of seed. I had 80½ pints from 1 pint of seed, exclusive of, perhaps, 2 pints given away and consumed before weighing. The bulk of the crop was grown under glass, as I considered the date (June 4) too late to risk outside sowing in our Scotch climate. I sowed one row out-of-doors, and the plants gave a fair crop, but, with other Beans, they were destroyed by frost on October 7. The Beans grown under glass were a splendid sample. *E. S. L., Berricks Hill.*

GROUND OPERATIONS (see pp. 179, 200, 231)—I have dug and trenched light ground early for many years, and always have secured good results. I have been told Mr. Edwin Beckett trenches light ground early, and heavy ground in the spring, when preparing ground for Onions. I should be greatly obliged to Mr. Beckett if he would state which is his practice. Many are pushing on the work of digging and trenching, on account of the scarcity, no matter what is the nature of the soil. Is heavy ground, trenched now, in a fit state in the spring to receive Onions, Leeks, and Cauliflowers raised under glass? Also is heavy soil sufficiently warm and dry for the plants to make satisfactory growth at the commencement? *C. Davis, Holy Wells Park Gardens, Ipswich.*

ECONOMY IN FUEL.—It behoves all to consider what can be done to economise fuel in the present scarcity of coke and coal, as well as enhanced prices. In some instances wood can be advantageously used, and choice fruits need not be forced so early as usual. *H.*

VANDA TERES. This Orchid requires a different treatment from others of its family. The plants have finished their season's growth, and should be given a long season of rest, affording only sufficient water to prevent the stems and terete leaves from shrivelling. They should be placed in a light position in a house having an intermediate temperature. Plants of *V. Hookeriana* and *V. Miss Joaquim* are still growing freely, and should be allowed to remain in their present quarters until growth is completed. *C.*

CROPS AND STOCK ON THE HOME FARM

RENOVATING PASTURES.

With a reduction of the grass average owing to the necessity for increasing the total crops, it becomes all to improve the remaining grass land, thereby increasing the feed for cows and hay for the winter.

Where grass fields are not too wet there should be no difficulty in procuring a full crop of grass or hay as required. Wet pastures may be improved by draining.

The present is a suitable time to undertake the work of renovating such pastures that have become impoverished owing to poverty of soil.

Many persons start renovating their pastures three months too late, and because an extra yield of grass is not obtained at once they are apt to blame the manure. Especially is this the case when applying basic slag; they do not stop to consider, or perhaps they do not know, that this manure is slow in action, and requires double the time to show its effect than most other fertilisers.

There is a wide choice of artificial manures well adapted for pastures. Farnyard manure, properly prepared and applied, is an excellent stimulant for grass, especially when mixed with wood ash, decayed vegetable matter, and road-side refuse. If the manure is not well decayed, allow the heap to remain for a month before spreading the material over the land. This compost forms a valuable, insulating fertilizer for grass, and should be spread evenly over the surface at the rate of 15 tons per acre. In a month, if the weather is dry, draw sharp-toothed iron harrows over the field to disintegrate the pieces and, by scratching the surface of the grass, the manure will come quicker into contact with the roots. The harrowing should be repeated at intervals until the whole of the manure disappears. Afterwards collect all stones and sticks, and finally roll the pasture to obtain a smooth surface for the grass cutter.

Of artificial manures for improving pastures basic slag is one of the best for lasting on almost any land, with the exception, perhaps, of sandy soils. Basic slag alone has the effect of inducing a free growth of clover among the grass, which is a valuable addition to the crop. When the subsoil is chalk, basic slag is usually effective, giving good results for five years afterwards. This fertilizer does not appear to be equally effective in all districts, but when kainit is added at the rate of 2½ cwt. per acre to every 5 cwt. of basic slag its effect is a large increase of grass. Some apply basic slag at the rate of 10 cwt. per acre. I prefer to apply that quantity in two applications with a four-year's interval.

The higher grades of basic slag may contain as much as 31 per cent. of soluble matter, and by using the higher grades there is a saving of labour in sowing, as less bulk is required. I am experimenting this season with some containing 42 per cent. of soluble matter.

Before sowing the slag it is well to harrow the surface, thus enabling the manure to more quickly reach the roots.

If the meadows cannot be shut off from cattle until March basic slag cannot be economically applied, therefore recourse should be had to some other stimulant, such as a good quality superphosphate of say, not less than 35 per cent. purity. This manure should be applied in March or the early part of April at the rate of 5 cwt. per acre. If the weather in May or June is dry this dressing may not show much effect on the hay crop, but it will stimulate the aftermath, which usually continues good right into the autumn and will be valuable in adding increased milk production. To give an immediate flip to the hay crop, sow 2 cwt. of sulphate of ammonia per acre evenly in April. This manure adds the growth of the finer grasses, thus adding to the quality of the hay.

Nitrate of soda, good though it is, is difficult to obtain, and sulphate of ammonia, a quick acting manure, is the best substitute.

For sandy soils guano and bone meal are valuable fertilisers, the former sown at the rate of 4 cwt. per acre in February or March and the latter in November, as it is slow of action, but lasting in its effects. E. McIvneuz.

MARKETS.

COVEY GARDEN, December 26

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quantity of the samples, the weights, which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—Eds.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various plants in pots and their average wholesale prices, including Aralia Sieboldii, Aspidistra plumosum, and Begonia Fochre de Lorraine.

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their average wholesale prices, including Anemone, Ranunculus, and Tulips.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and their average wholesale prices, including Viburnum, Camellia, and Aspidistra.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their average wholesale prices, including Artichoke, Cabbage, and Carrots.

Fruit: Average Wholesale Prices.

Table listing various fruits and their average wholesale prices, including Apples, Lemons, and Muscatels.

Obituary.

Mrs. BULL.—We regret to announce the death, on Saturday last the 22nd inst., in her 74th year, of Mrs. Bull, widow of the late William Bull, founder of Messrs. Bull's Nurseries, Chelsea.

GARDENING APPOINTMENT.

Mr. W. East, late Gardener to Sir Samuel Royle, Bart., Coppy Hill, Totteridge, Hertfordshire, as Gardener to Sir Philip Walehouse, Trosley Towers, Wokingham, Kent.

ANSWERS TO CORRESPONDENTS.

COLOUR OF FRUIT WALLS: J. J. C. Although black materials absorb the most and reflect the least amount of sun-heat, it is not wise to paint fruit walls black, for the trees would push into flower early, and be liable to a check in cold springs. Moreover, experiments have proved that trees grown against black walls do not ripen their fruit earlier than those on walls of ordinary colour. If the wall is full of crevices, offering hiding places for insect pests, the mortar should be repaired, and holes in the brickwork filled in. After this is done coat the brickwork with the following mixture: One peck of lime, half a peck of soil, and a quarter of a peck of sulphur, mixed in petroleum and skim milk in equal proportions, to the consistency of paint.

ORCHID LEAVES SPOTTED: Variegata. Orchid spot disease results in the collapse of the tissues affected, causing brown or blackish spots on leaves or bulbs. Imperfect nutrition from lack of healthy roots is a frequent cause of the disease, and every effort should be made to keep the plants clean and vigorous. If a plant is badly diseased it should be destroyed, but if only slightly affected it can often be restored to health by propagation, which grows the new parts of the plants from the worn out back portions. It is also beneficial to change the position of the plants in the house. Do not use paraffin emulsion or any paraffin spray.

PRUNING ROSES AND FRUIT TREES: J. A. Christie. The National Rose Society's Selected List of Roses and Instructions for Pruning, price 5s. 5d., and The Hand Book of Pruning, by James Udall, price 1s. 6d., would be suitable for your purpose. The books may be obtained from our Publishing Department at the prices given, which include postage.

SPRAY FOR APPLE SCAB: J. L. C. Lime-sulphur is as effective as Bordeaux mixture for Apple and Pear scab, and less likely to injure the foliage of tender varieties. See reply to W. O. in the last issue, p. 254.

WOOD ROT: W. B. It is rather difficult to know what is meant by your question. Wood rot is a diseased condition of the wood. We presume from the term "pickled wood" that cross-bred wood is referred to. If you wish to cross-bred wood against rot, the cross-bred may be procured from Messrs. English Bros., Ltd., Wisbech. Cross-bred wood is treated with oil of tar as a preservative.

Communications Received: H. I. W. R. W. R., W. E. W. T. H. J. G. W. J. F. S. A., (many thanks), C. O. L. P. J. E. C. E. F. & P. H. W., J. O. R. E. M., F. H. W. H.

Books as Presents

There is nothing so helpful to a young gardener as carefully selected books written by successful cultivators in the various branches of gardening.

- Botany, A Year's.** Adapted to Home and School Use. By Frances A. Kitchener. With 185 Illustrations. 5s. 4d.
- China, A Naturalist in Western.** By Ernest Henry Wilson. Illustrated, in Two Volumes. £1 10s. 6d.
- Flora, British, Handbook of the.** By Geo. Bentham. Revised by Sir Joseph Hooker. Seventh Edition. 9s. 5d.
- Fertilisers and Manures.** By A. D. Hall, F.R.S. 5s. 5d.
- Garden, Chemistry of the.** A Primer for Amateurs and Young Gardeners. By Herbert H. Cousins, M.A. 1s. 5d.
- Garden Craft in Europe.** By H. Inigo Triggs. £1 15s. 6d.
- Insect and Allied Pests of Orchard, Bush and Hothouse Fruits.** By F. V. Theobald, M.A., etc. 328 Illustrations. 30s. 6d.
- Insects, Injurious and Useful.** An Introduction to the Study of Economic Entomology. By L. C. Miall, F.R.S. 100 Illustrations. 3s. 9d.
- Intensive Culture of Vegetables on the French System.** By P. Aquatias. Illustrated 4s. 5d.
- Johnson's Gardener's Dictionary.** New Edition 9s. 6d.
- Judging, Rules for.** Issued by the Royal Horticultural Society. Latest Edition. 1s. 6d.
- Landscape Architecture, The Art of.** By Samuel Parsons. A practical and authoritative work. Illustrated. 18s. 6d.
- Lawns.** By Sutton and Sons, Reading. In paper cover. Well Illustrated. 1s. 3d.
- Lawns and Greens.** By T. W. Sanders. A Guide to the Formation and Management of Lawns, Tennis Courts, etc. Illustrated. Paper, 1s. 10d.
- Lily, Book of the.** By W. Goldring. Illustrated 2s. 9d.
- Little Gardens and How to Make the Most of Them.** By H. H. Thomas. A handy and useful work for the Amateur. Paper, 1s. 3d.; cloth, 1s. 9d.
- Mango, The.** By G. Marshall Woodrow. An account of its Culture and Varieties. 1s. 1d.
- Manures and the Principles of Manuring.** By C. M. Aikman. 6s. 10d.
- Manures for Garden and Farm Crops.** By W. Dyke. Cloth, 1s. 9d.
- Manuring, The Science and Practice of.** By W. Dyke, with introduction by J. Wright. A most practical work for the Amateur, Market and Professional Gardener. 1s. 2d.
- Manuring of Market Garden Crops, The.** By Bernard Dyer and F. W. L. Shrivell. New Edition. 1s. 3d.
- Mendelism.** By R. C. Punnett, F.R.S. New and Enlarged Edition. 5s. 4d.
- Mendel's Principles of Heredity.** By W. Bateson, F.R.S. 12s. 6d.
- Mushrooms, and How to Grow Them.** By John F. Barter. An excellent Treatise. Illustrated. 1s. 2d.
- My Garden in Spring.** By E. A. Bowles, M.A., Chairman of Scientific Committee of Royal Horticultural Society. With Preface by Reginald Farrer. "Mr. Bowles has the time to be his own gardener, and has thereby gained that first-hand knowledge of plants without which any writer on horticultural subjects is apt to be neither interesting nor informing." Price 5s. 6d.
- My Garden in Summer.** By the same author. Price 5s. 6d.
- My Garden in Autumn and Winter.** By the same author. 5s. 6d.
- Orchids and their Cultivation.** By James O'Brien, V.M.H., Hon. sec. of the R.H.S. Orchid Committee. Contains 8 full-page Coloured Plates from colour photography. 1s. 10d.
- Orchids: Their Culture and Management.** By W. Watson (Curator, Royal Botanic Gardens, Kew), and H. J. Chapman. Illustrated with 180 Engravings and 20 Coloured Plates 25s. 8d.
- Orchids, Fertilisation of.** By Chas Darwin. Illustrated. 3s. 11d.
- Orchid grower's Manual, The.** By the late B. S. Williams. 800 pages. Numerous Illustrations. 16s. 6d.
- Pansies, Violas and Violets.** By W. Cuthbertson and R. Hooper Pearson. With 8 full-page Coloured Plates from colour photography. 1s. 10d.
- Pansies and Violets.** By D. B. Crane. Paper, 1s. 2d.; cloth, 1s. 9d.
- Peach, The Book of the.** By H. W. Ward. A Practical Handbook on the Cultivation of Peaches and Nectarines under Glass and Out of doors. 2s. 10d.
- Pears and Plums, The Book of.** By the Rev. E. Bartrum, D.D. Illustrated. 2s. 9d.
- Pinus, The Genus.** By George Russell Shaw. Price £2 15s. 6d.
- Plant Breeding.** Being Five Lectures upon the Amelioration of Domestic Plants. By Prof. L. H. Bailey. Illustrated. 8s. 11d.
- Plant Life.** By C. A. Hall. £1 0s. 6d.
- Practical Plant Physiology.** By Frederick Keeble, F.R.S. Illustrated. 5s. 10d.
- Practical Tree Repair.** By Elbert Peets. The Physical Repair of Trees—Bracing and the Treatment of Wounds and Cavities. Illustrated. 7s. 11d.
- Plants and Trees, Diseases of Cultivated.** By George Massee. Well Illustrated. 7s. 11d.
- Plants, A Popular Treatise on the Physiology of.** By Dr. Paul Srauer. Translated by F. E. Weiss, D.Sc. With 33 Illustrations. 9s. 6d.
- Primula, Handbook of the Hardy.** By H. M. Paul. An Illustrated Work on the Culture, Mode of Growth and Utility of Primulas. 1s. 1d.
- Pruning, The Handy Book of.** With Chapters on Grafting and Budding. By James Udale, with introduction by the Right Hon. Viscount Cobham. New Edition. Illustrated. 1s. 9d.
- Rhododendrons and Azaleas.** By W. Watson. With preface by Sir. F. W. Moore, F.L.S. (The first popular volume published on this subject.) 8 full-page Coloured Plates. 1s. 10d.
- Rock Gardens.** By Reginald Farrer. With Preface by Dr. J. Bretland Farmer, F.R.S. Contains 8 Coloured Plates. 1s. 10d.
- Rock Garden, The English.** By Reginald Farrer. A complete dictionary of Hardy Plants suitable for Rock Garden Culture. Contains 500,000 words and 300 Illustrations. In 2 Vols. Price, £2 2s. 10d. post free (in the press).
- Root and Stem Vegetables.** By the late Alexander Dean. Contains 8 full-page Coloured Plates. 1s. 10d.
- Rose, The Book of the.** By Rev. A. Foster-Melliar, M.A. Illustrated. New Edition. 5s. 5d.
- Roses.** By H. R. Darlington. Contains 8 full-page Coloured Plates. 2s. 11d.
- Roses for the Garden and Greenhouse.** By John Weathers. Description, Culture, Propagation, Manures, etc. Coloured Illustrations. 5s. 4d.
- Roses in Pots.** By Wm. Paul. Ninth Edition. An invaluable Guide to the Cultivation of Roses in Pots, whether for forcing or otherwise. 2s. 2d.
- Salads and their Cultivation.** By T. W. Sanders. How to grow them in the Open, on Hot Beds, and Under Glass, etc. Freely Illustrated. Paper, 1s. 3d.
- Saxifrages or Rocklofts.** By W. Irving and R. A. Malby. A practical work on the Culture of Saxifrages. Well Illustrated in Colour and Half-tones. 2s. 10d.
- Soil, The.** By A. D. Hall, F.R.S. An introduction to the Scientific Study of the Growth of Crops. New Edition. 5s. 5d.
- Species and Varieties, their Origin by Mutation.** By Prof. Inigo De Vries. Second Edition. 21s. 6d.
- Trees and Shrubs, Beautiful Flowering, for British and Irish Gardens.** By John Weathers. Description, Culture, Planting, Pruning, Propagation, etc. Coloured Illustrations. 3s. 10d.
- Vegetables and Flowers, The Culture of, from Seeds and Roots.** By Sutton and Sons, Reading. New Edition. 5s. 6d.
